FD176X-02

Floppy Disk Formatter/Controller Family

FD176X-02

FEATURES

- 1 MHZ VERSION OF FD179X
- TWO VFO CONTROL SIGNALS — RG & VFOE
- SOFT SECTOR FORMAT COMPATIBILITY
- AUTOMATIC TRACK SEEK WITH VERIFICATION
- ACCOMMODATES SINGLE AND DOUBLE DENSITY
- READ MODE
 - Single/Multiple Sector Read with Automatic Search or Entire Track Read
- Selectable 128, 256, 512 or 1024 Byte Sector Lengths
- WRITE MODE
 - Single/Multiple Sector Write with Automatic Sector Search
 - Entire Track Write for Diskette Formatting
- SYSTEM COMPATIBILITY
 - Double Buffering of Data 8 Bit Bi-Directional Bus for Data, Control and Status
 - DMA or Programmed Data Transfers
 - All Inputs and Outputs are TTL Compatible
 - On-Chip Track and Sector Registers/Comprehensive Status Information
- PROGRAMMABLE CONTROLS
 - Selectable Track to Track Stepping Time
 - Side Select Compare

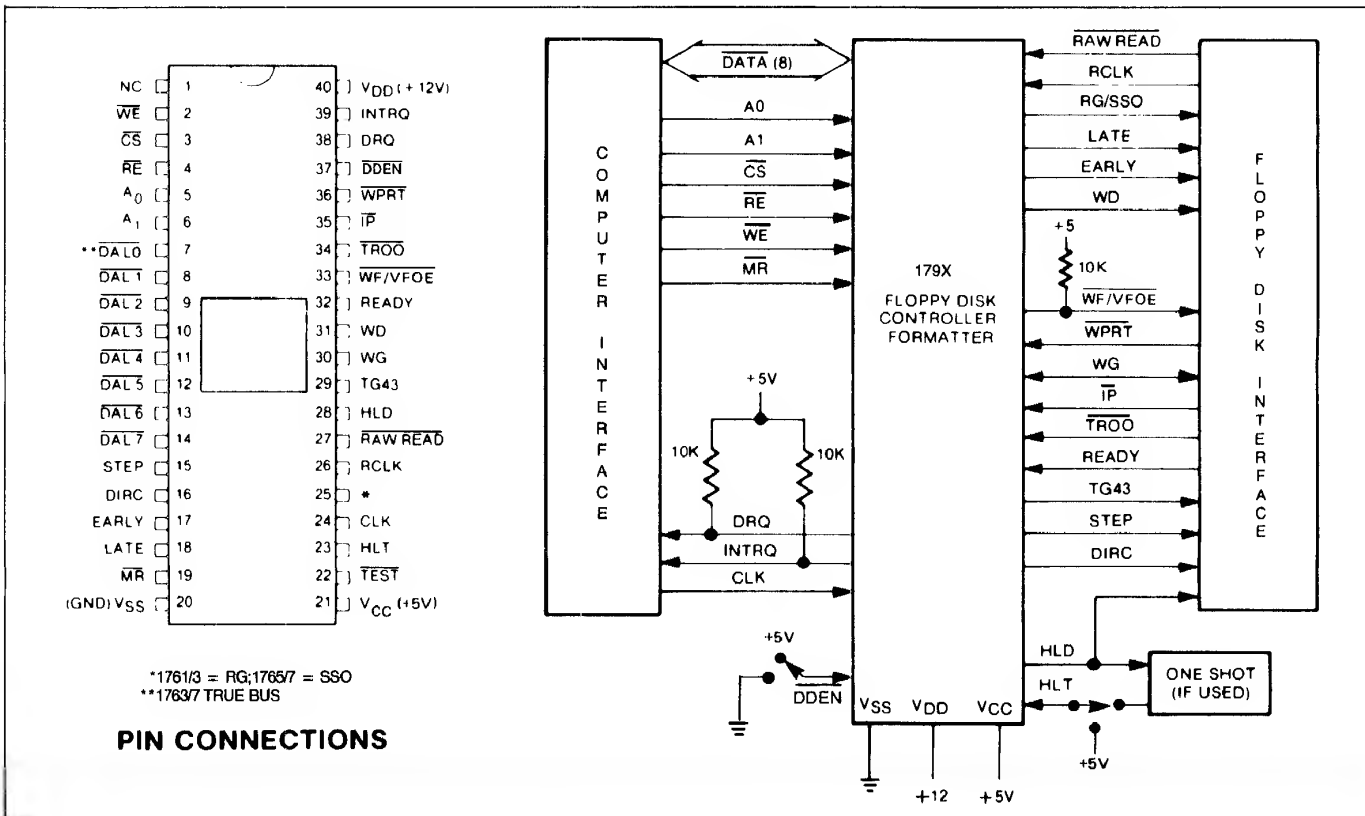

- WRITE PRECOMPENSATION
- WINDOW EXTENSION
- INCORPORATES ENCODING/DECODING AND ADDRESS MARK CIRCUITRY
- INTERFACES TO WD1691 DATA SEPARATOR

FD176X SYSTEM BLOCK DIAGRAM

PIN OUTS

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION																									
1	NO CONNECTION	NC	Pin 1 is internally connected to a back bias generator and must be left open by the user.																									
19	MASTER RESET	MR	A logic low (50 microseconds min.) on this input resets the device and loads HEX 03 into the command register. The Not Ready (Status Bit 7) is reset during MR ACTIVE. When MR is brought to a logic high a RESTORE Command is executed, regardless of the state of the Ready signal from the drive. Also, HEX 01 is loaded into sector register.																									
20	POWER SUPPLIES	Vss	Ground																									
21		Vcc	+5V ± 5%																									
40		Vdd	+12V ± 5%																									
COMPUTER INTERFACE:																												
2	WRITE ENABLE	WE	A logic low on this input gates data on the DAL into the selected register when CS is low.																									
3	CHIP SELECT	CS	A logic low on this input selects the chip and enables computer communication with the device.																									
4	READ ENABLE	RE	A logic low on this input controls the placement of data from a selected register on the DAL when CS is low.																									
5,6	REGISTER SELECT LINES	A0, A1	These inputs select the register to receive/transfer data on the DAL lines under RE and WE control: <table><tr><td>CS</td><td>A1</td><td>A0</td><td>RE</td><td>WE</td></tr><tr><td>0</td><td>0</td><td>0</td><td>Status Reg</td><td>Command Reg</td></tr><tr><td>0</td><td>0</td><td>1</td><td>Track Reg</td><td>Track Reg</td></tr><tr><td>0</td><td>1</td><td>0</td><td>Sector Reg</td><td>Sector Reg</td></tr><tr><td>0</td><td>1</td><td>1</td><td>Data Reg</td><td>Data Reg</td></tr></table>	CS	A1	A0	RE	WE	0	0	0	Status Reg	Command Reg	0	0	1	Track Reg	Track Reg	0	1	0	Sector Reg	Sector Reg	0	1	1	Data Reg	Data Reg
CS	A1	A0	RE	WE																								
0	0	0	Status Reg	Command Reg																								
0	0	1	Track Reg	Track Reg																								
0	1	0	Sector Reg	Sector Reg																								
0	1	1	Data Reg	Data Reg																								
7-14	DATA ACCESS LINES	DAL0-DAL7	Eight bit Bidirectional bus used for transfer of data, control, and status. This bus is receiver enabled by WE or transmitter enabled by RE. Each line will drive 1 standard TTL load.																									
24	CLOCK	CLK	This input requires a free-running 1 MHZ ± 1% 50% duty cycle square wave clock for internal timing reference.																									
38	DATA REQUEST	DRQ	This open drain output indicates that the DR contains assembled data in Read operations, or the DR is empty in Write operations. This signal is reset when serviced by the computer through reading or loading the DR in Read or Write operations, respectively. Use 10K pull-up resistor to +5.																									
39	INTERRUPT REQUEST	INTRQ	This open drain output is set at the completion of any command and is reset when the STATUS register is read or the command register is written to. Use 10K pull-up resistor to +5.																									
FLOPPY DISK INTERFACE:																												
15	STEP	STEP	The step output contains a pulse for each step.																									
16	DIRECTION	DIRC	Direction Output is active high when stepping in, active low when stepping out.																									
17	EARLY	EARLY	Indicates that the WRITE DATA pulse occurring while Early is active (high) should be shifted early for write precompensation.																									
18	LATE	LATE	Indicates that the write data pulse occurring while Late is active (high) should be shifted late for write precompensation.																									

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
22	TEST	TEST	This input is used for testing purposes only and should be tied to +5V or left open by the user unless interfacing to voice coil actuated steppers.
23	HEAD LOAD TIMING	HLT	When a logic high is found on the HLT input the head is assumed to be engaged. It is typically derived from a 1 shot triggered by HLD.
25	READ GATE (1761, 1763)	RG	This output is used for synchronization of external data separators. The output goes high after two Bytes of zeros in single density, or 4 Bytes of either zeros or ones in double density operation.
25	SIDE SELECT OUTPUT (1765, 1767)	SSO	The logic level of the Side Select Output is directly controlled by the 'S' flag in Type II or III commands. When U = 1, SSO is set to a logic 1. When U = 0, SSO is set to a logic 0. The SSO is compared with the side information in the Sector I.D. Field. If they do not compare Status Bit 4 (RNF) is set. The Side Select Output is only updated at the beginning of a Type II or III command. It is forced to a logic 0 upon a MASTER RESET condition.
26	READ CLOCK	RCLK	A nominal square-wave clock signal derived from the data stream must be provided to this input. Phasing (i.e. RCLK transitions) relative to RAW READ is important but polarity (RCLK high or low) is not.
27	RAW READ	RAW READ	The data input signal directly from the drive. This input shall be a negative pulse for each recorded flux transition.
28	HEAD LOAD	HLD	The HLD output controls the loading of the Read-Write head against the media.
29	TRACK GREATER THAN 43	TG43	This output informs the drive that the Read/Write head is positioned between tracks 44-76. This output is valid only during Read and Write Commands.
30	WRITE GATE	WG	This output is made valid before writing is to be performed on the diskette.
31	WRITE DATA	WD	A 400 ns (MFM) or 1000 ns (FM) output pulse per flux transition. WD contains the unique Address marks as well as data and clock in both FM and MFM formats.
32	READY	READY	This input indicates disk readiness and is sampled for a logic high before Read or Write commands are performed. If Ready is low the Read or Write operation is not performed and an interrupt is generated. Type I operations are performed regardless of the state of Ready. The Ready input appears in inverted format as Status Register bit 7.
33	WRITE FAULT VFO ENABLE	WF/VFOE	This is a bi-directional signal used to signify writing faults at the drive, and to enable the external PLO data separator. When WG = 1, Pin 33 functions as a WF input. If WF = 0, any write command will immediately be terminated. When WG = 0, Pin 33 functions as a VFOE output. VFOE will go low during a read operation after the head has loaded and settled (HLT = 1). On the 1765/7, it will remain low until the last bit of the second CRC byte in the ID field. VFOE will then go high until 8 bytes (MFM) or 4 bytes (FM) before the Address Mark. It will then go active until the last bit of the second CRC byte of the Data Field. On the 1761/3, VFOE will remain low until the end of the Data Field. This pin has an internal 100K Ohm pull-up resistor.
34	TRACK 00	TR00	This input informs the FD176X that the Read/Write head is positioned over Track 00.

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
35	INDEX PULSE	IP	This input informs the FD176X when the index hole is encountered on the diskette.
36	WRITE PROTECT	WPRT	This input is sampled whenever a Write Command is received. A logic low terminates the command and sets the Write Protect Status bit.
37	DOUBLE DENSITY	DDEN	This input pin selects either single or double density operation. When DDEN = 0, double density is selected. When DDEN = 1, single density is selected.

GENERAL DESCRIPTION

The FD176X are N-Channel Silicon Gate MOS LSI devices which perform the functions of a Floppy Disk Formatter/Controller in a single chip implementation. The FD176X is IBM 3740 compatible in single density mode (FM) and System 34 compatible in Double Density Mode (MFM). The FD176X contains all the features of its predecessor the FD1771, plus the added features necessary to read/write and format a double density diskette. These include address mark detection, FM and MFM encode and decode logic, window extension, and write precompensation. In order to maintain compatibility, the FD1771, FD1781, and FD176X designs were made as close as possible with the computer interface, instruction set, and I/O registers being identical. Also, head load control is identical. In each case, the actual pin assignments vary by only a few pins from any one to another.

The processor interface consists of an 8-bit bi-directional bus for data, status, and control word transfers. The FD176X is set up to operate on a multiplexed bus with other bus-oriented devices.

The FD176X is TTL compatible on all inputs and outputs. The outputs will drive ONE TTL load or three LS loads. The 1763 is identical to the 1761 except the DAL lines are TRUE for systems that utilize true data busses.

The 1765/7 has a side select output for controlling double sided drives.

ORGANIZATION

The Floppy Disk Formatter block diagram is illustrated on page 5. The primary sections include the parallel processor interface and the Floppy Disk interface.

Data Shift Register — This 8-bit register assembles serial data from the Read Data input (RAW READ) during Read operations and transfers serial data to the Write Data output during Write operations.

Data Register — This 8-bit register is used as a holding register during Disk Read and Write operations. In Disk Read operations the assembled data byte is transferred in parallel to the Data Register from the Data Shift Register. In Disk Write operations information is transferred in parallel from the Data Register to the Data Shift Register.

When executing the Seek command the Data Register holds the address of the desired Track position. This register is loaded from the DAL and gated onto the DAL under processor control.

Track Register — This 8-bit register holds the track number of the current Read/Write head position. It is incremented by one every time the head is stepped in (towards track 76) and decremented by one when the head is stepped out (towards track 00). The contents of the register are compared with the recorded track number in the ID field during disk Read, Write, and Verify operations. The Track Register can be loaded from or transferred to the DAL. This Register should not be loaded when the device is busy.

Sector Register (SR) — This 8-bit register holds the address of the desired sector position. The contents of the register are compared with the recorded sector number in the ID field during disk Read or Write operations. The Sector Register contents can be loaded from or transferred to the DAL. This register should not be loaded when the device is busy.

Command Register (CR) — This 8-bit register holds the command presently being executed. This register should not be loaded when the device is busy unless the new command is a force interrupt. The command register can be loaded from the DAL, but not read onto the DAL.

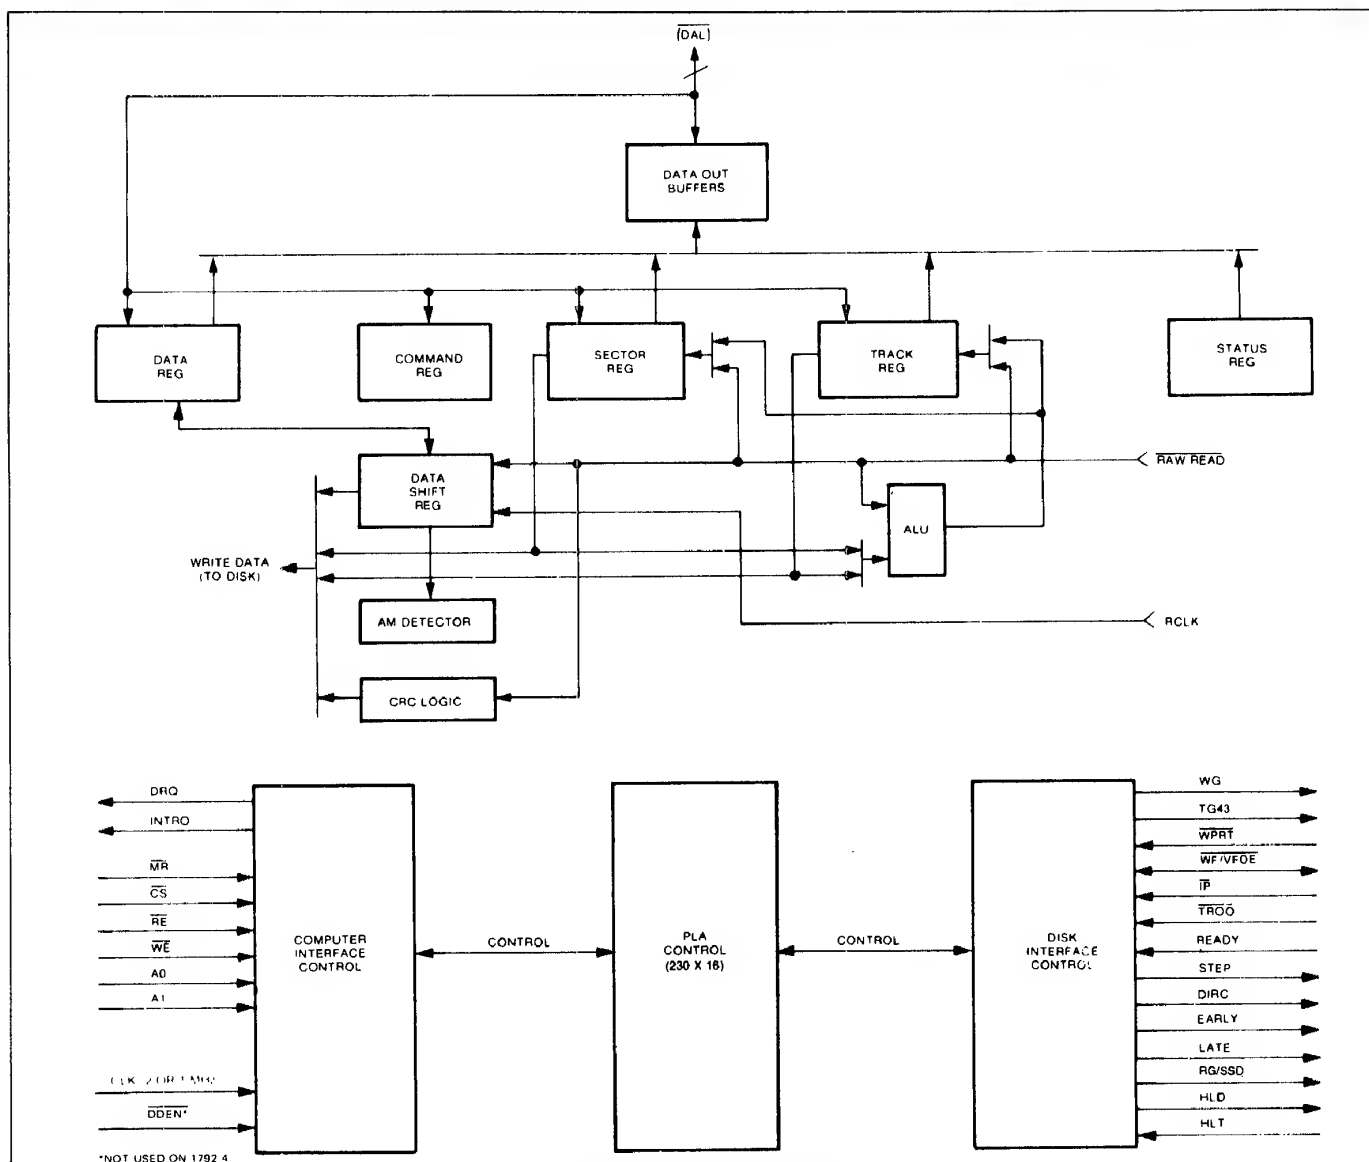

Status Register (STR) — This 8-bit register holds device Status information. The meaning of the Status bits is a function of the type of command previously executed. This register can be read onto the DAL, but not loaded from the DAL.

CRC Logic — This logic is used to check or to generate the 16-bit Cyclic Redundancy Check (CRC). The polynomial is: $G(x) = x^{16} + x^{12} + x^5 + 1$.

The CRC includes all information starting with the address mark and up to the CRC characters. The CRC register is preset to ones prior to data being shifted through the circuit.

Arithmetic/Logic Unit (ALU) — The ALU is a serial comparator, incrementer, and decrements and is used for register modification and comparisons with the disk recorded ID field.

Timing and Control — All computer and Floppy Disk Interface controls are generated through this logic. The internal device timing is generated from an external crystal clock.

FD176X BLOCK DIAGRAM

The FD176X has two different modes of operation according to the state of $\overline{\text{DDEN}}$. When $\overline{\text{DDEN}} = 0$ double density (MFM) is assumed. When $\overline{\text{DDEN}} = 1$, single density (FM) is assumed.

AM Detector — The address mark detector detects ID, data and index address marks during read and write operations.

PROCESSOR INTERFACE

The interface to the processor is accomplished through the eight Data Access Lines (DAL) and associated control signals. The DAL are used to transfer Data, Status, and Control words out of, or into the FD176X. The DAL are three state buffers that are enabled as output drivers when Chip Select ($\overline{\text{CS}}$) and Read Enable ($\overline{\text{RE}}$) are active (low logic state) or act as input receivers when $\overline{\text{CS}}$ and Write Enable ($\overline{\text{WE}}$) are active.

When transfer of data with the Floppy Disk Controller is required by the host processor, the device address is decoded and $\overline{\text{CS}}$ is made low. The address bits A1 and A0,

combined with the signals $\overline{\text{RE}}$ during a Read operation or $\overline{\text{WE}}$ during a Write operation are interpreted as selecting the following registers:

A1 - A0	READ ($\overline{\text{RE}}$)	WRITE ($\overline{\text{WE}}$)
0 0	Status Register	Command Register
0 1	Track Register	Track Register
1 0	Sector Register	Sector Register
1 1	Data Register	Data Register

During Direct Memory Access (DMA) types of data transfers between the Data Register of the FD176X and the processor, the Data Request (DRQ) output is used in Data Transfer control. This signal also appears as status bit 1 during Read and Write operations.

On Disk Read operations the Data Request is activated (set high) when an assembled serial input byte is transferred in parallel to the Data Register. This bit is cleared when the Data Register is read by the processor. If the Data Register is read after one or more characters are lost, by having new

data transferred into the register prior to processor readout, the Lost Data bit is set in the Status Register. The Read operation continues until the end of sector is reached.

On Disk Write operations the data Request is activated when the Data Register transfers its contents to the Data Shift Register, and requires a new data byte. It is reset when the Data Register is loaded with new data by the processor. If new data is not loaded at the time the next serial byte is required by the Floppy Disk, a byte of zeroes is written on the diskette and the Lost Data bit is set in the Status Register.

At the completion of every command an INTRQ is generated. INTRQ is reset by either reading the status register or by loading the command register with a new command. In addition, INTRQ is generated if a Force Interrupt command condition is met.

The 176X has two modes of operation according to the state of $\overline{\text{DDEN}}$ (Pin 37). When $\overline{\text{DDEN}} = 1$, single density is selected. In either case, the CLK input (Pin 24) is at 1 MHz.

GENERAL DISK READ OPERATIONS

Sector lengths of 128, 256, 512 or 1024 are obtainable in either FM or MFM formats. For FM, $\overline{\text{DDEN}}$ should be placed to logical "1." For MFM formats, $\overline{\text{DDEN}}$ should be placed to a logical "0." Sector lengths are determined at format time by the fourth byte in the "ID" field.

Sector Length Table*	
Sector Length Field (hex)	Number of Bytes in Sector (decimal)
00	128
01	256
02	512
03	1024

*1765/67 may vary — see command summary.

The number of sectors per track as far as the FD176X is concerned can be from 1 to 255 sectors. The number of tracks as far as the FD176X is concerned is from 0 to 255 tracks.

For read operations in 5¼" double density the FD176X requires RAW READ Data (Pin 27) signal which is a 400 ns pulse per flux transition and a Read clock (RCLK) signal to indicate flux transition spacings. The RCLK (Pin 26) signal is provided by some drives but if not it may be derived externally by Phase lock loops, one shots, or counter techniques. In addition, a Read Gate Signal is provided as an output (Pin 25) on 1761/63 which can be used to inform phase lock loops when to acquire synchronization. When reading from the media in FM, RG is made true when 2 bytes of zeroes are detected. The FD176X must find an address mark within the next 10 bytes; otherwise RG is reset and the search for 2 bytes of zeroes begins all over again. If an address mark is found within 10 bytes, RG remains true as long as the FD176X is deriving any useful information from the data stream. Similarly for MFM, RG is made active when 4 bytes of "00" or "FF" are detected. The FD176X must find an address mark within the next 16 bytes, otherwise RG is reset and search resumes.

During read operations ($\text{WG} = 0$), the $\overline{\text{VFOE}}$ (Pin 33) is provided for phase lock loop synchronization. $\overline{\text{VFOE}}$ will go active low when:

- Both HLT and HLD are True
- Settling Time, if programmed, has expired
- The 176X is inspecting data off the disk

If $\overline{\text{WF}}/\overline{\text{VFOE}}$ is not used, this pin may be left open, as it has an internal pull-up resistor.

GENERAL DISK WRITE OPERATION

When writing is to take place on the diskette the Write Gate (WG) output is activated, allowing current to flow into the Read/Write head. As a precaution to erroneous writing the first data byte must be loaded into the Data Register in response to a Data Request from the FD176X before the Write Gate signal can be activated.

Writing is inhibited when the Write Protect input is a logic low, in which case any Write command is immediately terminated, an interrupt is generated and the Write Protect status bit is set. The Write Fault input, when activated, signifies a writing fault condition detected in disk drive electronics such as failure to detect write current flow when the Write Gate is activated. On detection of this fault the FD176X terminates the current command, and sets the Write Fault bit (bit 5) in the Status Word. The Write Fault input should be made inactive when the Write Gate output becomes inactive.

For write operations, the FD176X provides Write Gate (Pin 30) and Write Data (Pin 31) outputs. Write data consists of a series of 1000 ns pulses in FM ($\overline{\text{DDEN}} = 1$) and 400 ns pulses in MFM ($\overline{\text{DDEN}} = 0$). Write Data provides the unique address marks in both formats.

Also during write, two additional signals are provided for write precompensation. These are EARLY (Pin 17) and LATE (Pin 18). EARLY is active true when the WD pulse appearing on (Pin 30) is to be written EARLY. LATE is active true when the WD pulse is to be written LATE. If both EARLY and LATE are low when the WD pulse is present, the WD pulse is to be written at nominal. Since write precompensation values vary from disk manufacturer to disk manufacturer, the actual value is determined by several one shots or delay lines which are located external to the FD176X. The write precompensation signals EARLY and LATE are valid for the duration of WD in both FM and MFM formats.

READY

Whenever a Read or Write command (Type II or III) is received the FD176X samples the Ready input. If this input is logic low the command is not executed and an interrupt is generated. All Type I commands are performed regardless of the state of the Ready input. Also, whenever a Type II or III command is received, the TG43 signal output is updated.

COMMAND DESCRIPTION

The FD176X will accept eleven commands. Command words should only be loaded in the Command Register when the Busy status bit is off (Status bit 0). The one

exception is the Force Interrupt command. Whenever a command is being executed, the Busy status bit is set. When a command is completed, an interrupt is generated and the Busy status bit is reset. The Status Register

indicates whether the completed command encountered an error or was fault free. For ease of discussion, commands are divided into four types. Commands and types are summarized in Table 1.

TABLE 1. COMMAND SUMMARY

A. Commands for Models: 1761, 1763

B. Commands for Models: 1765, 1767

Type	Command	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
I	Restore	0	0	0	0	h	V	r1	r0	0	0	0	0	h	V	r1	r0
I	Seek	0	0	0	1	h	V	r1	r0	0	0	0	1	h	V	r1	r0
I	Step	0	0	1	T	h	V	r1	r0	0	0	1	T	h	V	r1	r0
I	Step-in	0	1	0	T	h	V	r1	r0	0	1	0	T	h	V	r1	r0
I	Step-out	0	1	1	T	h	V	r1	r0	0	1	1	T	h	V	r1	r0
II	Read Sector	1	0	0	m	S	E	C	0	1	0	0	m	L	E	U	0
II	Write Sector	1	0	1	m	S	E	C	a0	1	0	1	m	L	E	U	a0
III	Read Address	1	1	0	0	0	E	0	0	1	1	0	0	0	E	U	0
III	Read Track	1	1	1	0	0	E	0	0	1	1	1	0	0	E	U	0
III	Write Track	1	1	1	1	0	E	0	0	1	1	1	1	0	E	U	0
IV	Force Interrupt	1	1	0	l1	l3	l2	l1	l0	1	1	0	1	l3	l2	l1	l0

TABLE 2. FLAG SUMMARY

FLAG SUMMARY

Command Type	Bit No(s)	Description																					
I	0, 1	r1 r0 = Stepping Motor Rate See Table 3 for Rate Summary																					
I	2	V = Track Number Verify Flag	V = 0, No verify V = 1, Verify on destination track

L = 0	256	512	1024	128																			
L = 1	128	256	512	1024																			

FLAG SUMMARY

Command Type	Bit No(s)	Description
II	4	m = Multiple Record Flag m = 0, Single record m = 1, Multiple records
IV	0-3	I _x = Interrupt Condition Flags I ₀ = 1 Not Ready To Ready Transition I ₁ = 1 Ready To Not Ready Transition I ₂ = 1 Index Pulse I ₃ = 1 Immediate Interrupt, Requires A Reset I _{3-I1} = 0 Terminate With No Interrupt (INTRQ)

*NOTE: See Type IV Command Description for further information.

TYPE I COMMANDS

The Type I Commands include the Restore, Seek, Step, Step-In, and Step-Out commands. Each of the Type I Commands contains a rate field (R₀ R₁), which determines the stepping motor rate as defined in Table 3.

A 4 μ s (MFM) or 8 μ s (FM) pulse is provided as an output to the drive. For every step pulse issued, the drive moves one track location in a direction determined by the direction output. The chip will step the drive in the same direction it last stepped unless the command changes the direction.

The Direction signal is active high when stepping in and low when stepping out. The Direction signal is valid 24 μ s before the first stepping pulse is generated.

The rates (shown in Table 3) can be applied to a Step-Direction Motor through the device interface.

TABLE 3. STEPPING RATES

DDEN R1 R0	0 TEST=1	1 TEST=1	x TEST=0
0 0	6 ms	6 ms	368 μ s
0 1	12 ms	12 ms	380 μ s
1 0	20 ms	20 ms	396 μ s
1 1	30 ms	30 ms	416 μ s

After the last directional step an additional 30 milliseconds of head settling time takes place if the Verify flag is set in Type I commands. If $\overline{\text{TEST}} = 0$, there is zero settling time. There is also a 30 ms head settling time if the E flag is set in any Type II or III command.

When a Seek, Step or Restore command is executed an optional verification of Read-Write head position can be performed by settling bit 2 (V = 1) in the command word to a logic 1. The verification operation begins at the end of the 30 millisecond settling time after the head is loaded against the media. The track number from the first encountered ID Field is compared against the contents of the Track Register. If the track numbers compare and the ID Field Cyclic Redundancy Check (CRC) is correct, the verify operation is complete and an INTRQ is generated with no errors. If there is a match but not a valid CRC, the CRC error

status bit is set (Status bit 3), and the next encountered ID field is read from the disk for the verification operation.

The FD176X must find an ID field with correct track number and correct CRC within 5 revolutions of the media; otherwise the seek error is set and an INTRQ is generated. If V = 0, no verification is performed.

The Head Load (HLD) output controls the movement of the read/write head against the media. HLD is activated at the beginning of a Type I command if the h flag is set (h = 1), at the end of the Type I command if the verify flag (V = 1), or upon receipt of any Type II or III command. Once HLD is active it remains active until either a Type I command is received with (h = 0 and V = 0); or if the FD176X is in an idle state (non-busy) and 15 index pulses have occurred.

Head Load timing (HLT) is an input to the FD176X which is used for the head engage time. When HLT = 1, the FD176X assumes the head is completely engaged. The head engage time is typically 30 to 100 ms depending on drive. The low to high transition on HLT is typically used to fire a one shot. The output of the one shot is then used for HLT and supplied as an input to the FD176X.

HEAD LOAD TIMING

When both HLD and HLT are true, the FD176X will then read from or write to the media. The "and" of HLD and HLT appears as status Bit 5 in Type I status.

In summary for the Type I commands: if h = 0 and V = 0, HLD is reset. If h = 1 and V = 0, HLD is set at the beginning of the command and HLT is not sampled nor is there an internal 30 ms delay. If h = 0 and V = 1, HLD is set near the end of the command, an internal 30 ms occurs, and the FD176X waits for HLT to be true. If h = 1 and V = 1, HLD is set at the beginning of the command. Near the end of the command, after all the steps have been issued, an internal 30 ms delay occurs and the FD176X then waits for HLT to occur.

For Type II and III commands with E flag off, HLD is made active and HLT is sampled until true. With E flag on, HLD is made active, an internal 30 ms delay occurs and then HLT is sampled until true.

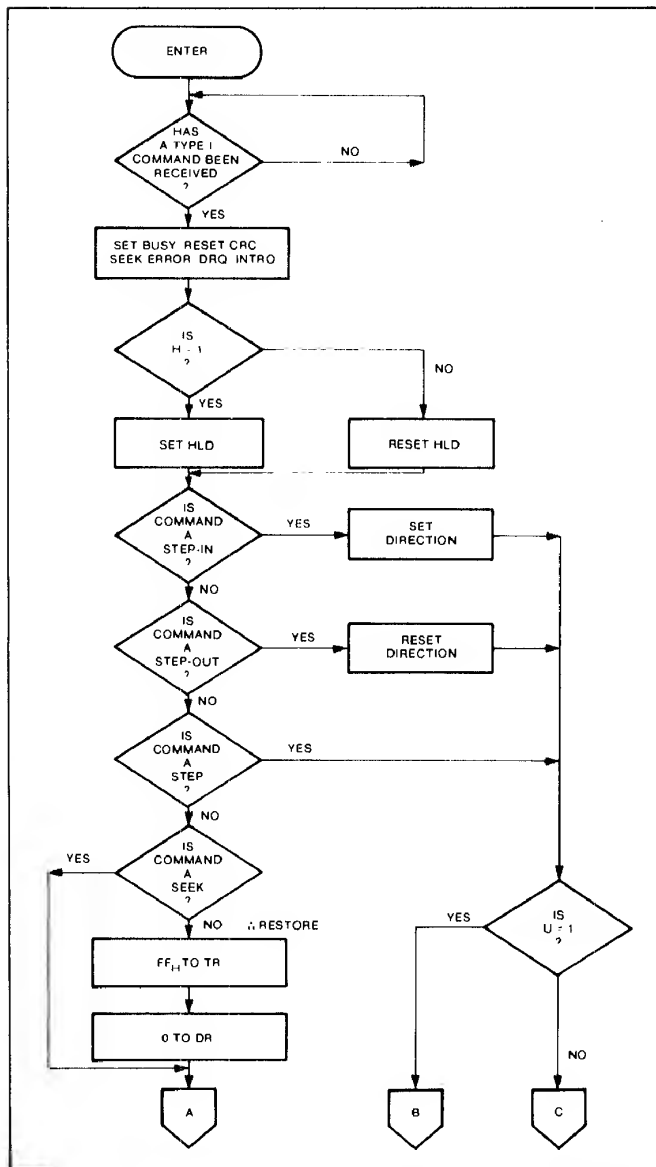

RESTORE (SEEK TRACK 0)

Upon receipt of this command the Track 00 ($\overline{TR}00$) input is sampled. If $\overline{TR}00$ is active low indicating the Read-Write head is positioned over track 0, the Track Register is loaded with zeroes and an interrupt is generated. If $\overline{TR}00$ is not active low, stepping pulses (pins 15 to 16) at a rate specified by the R1 R0 field are issued until the $\overline{TR}00$ input is activated. At this time the Track Register is loaded with zeroes and an interrupt is generated. If the $\overline{TR}00$ input does not go active low after 255 stepping pulses, the FD176X terminates operation, interrupts, and sets the Seek error status bit providing the V flag is set. A verification operation also takes place if the V flag is set. The h bit allows the head to

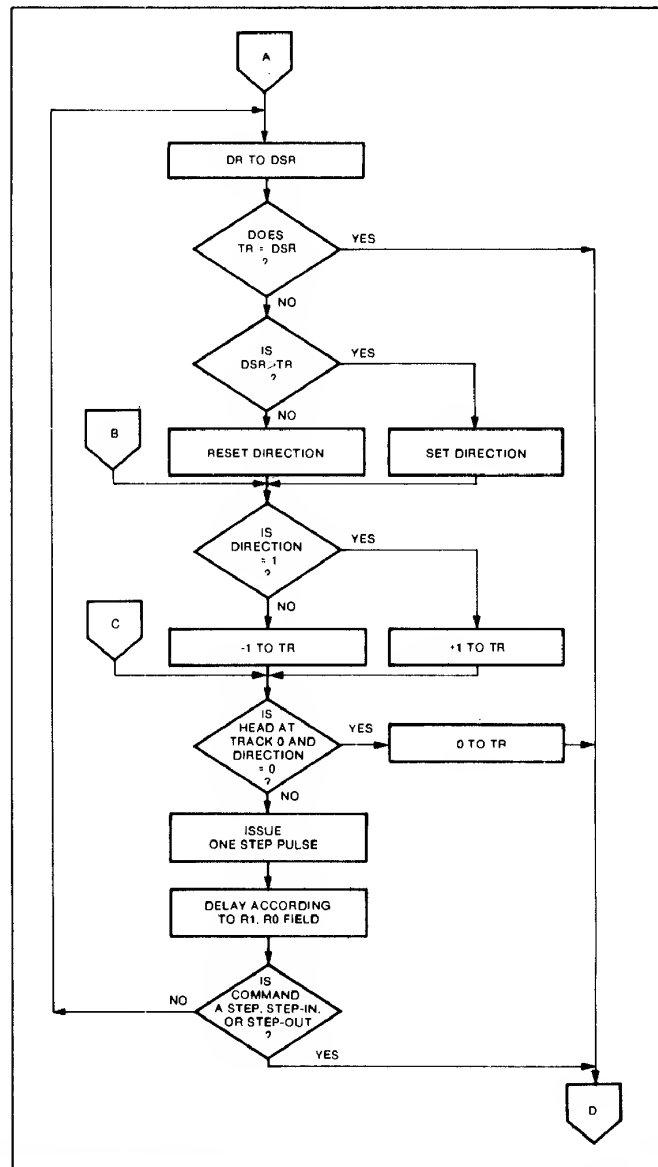

be loaded at the start of command. Note that the Restore command is executed when \overline{MR} goes from an active to an inactive state and that the DRQ pin stays low.

SEEK

This command assumes that the Track Register contains the track number of the current position of the Read-Write head and the Data Register contains the desired track number. The FD176X will update the Track register and issue stepping pulses in the appropriate direction until the contents of the Track register are equal to the contents of the Data Register (the desired track location). A verification operation takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command. Note: When using multiple drives, the track register must be updated for the drive selected before seeks are issued.

TYPE I COMMAND FLOW

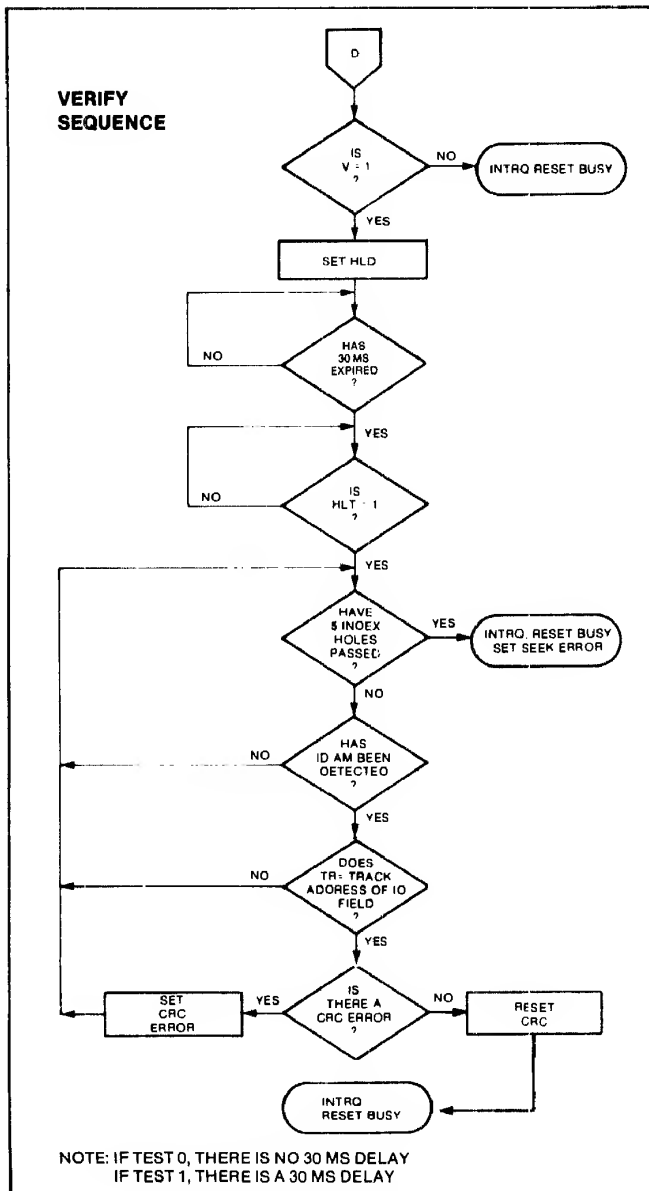

TYPE I COMMAND FLOW

STEP

Upon receipt of this command, the FD176X issues one stepping pulse to the disk drive. The stepping motor direction is the same as in the previous step command. After a delay determined by the r1r0 field, a verification takes place if the V flag is on. If the U flag is on, the Track Register is updated. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP-IN

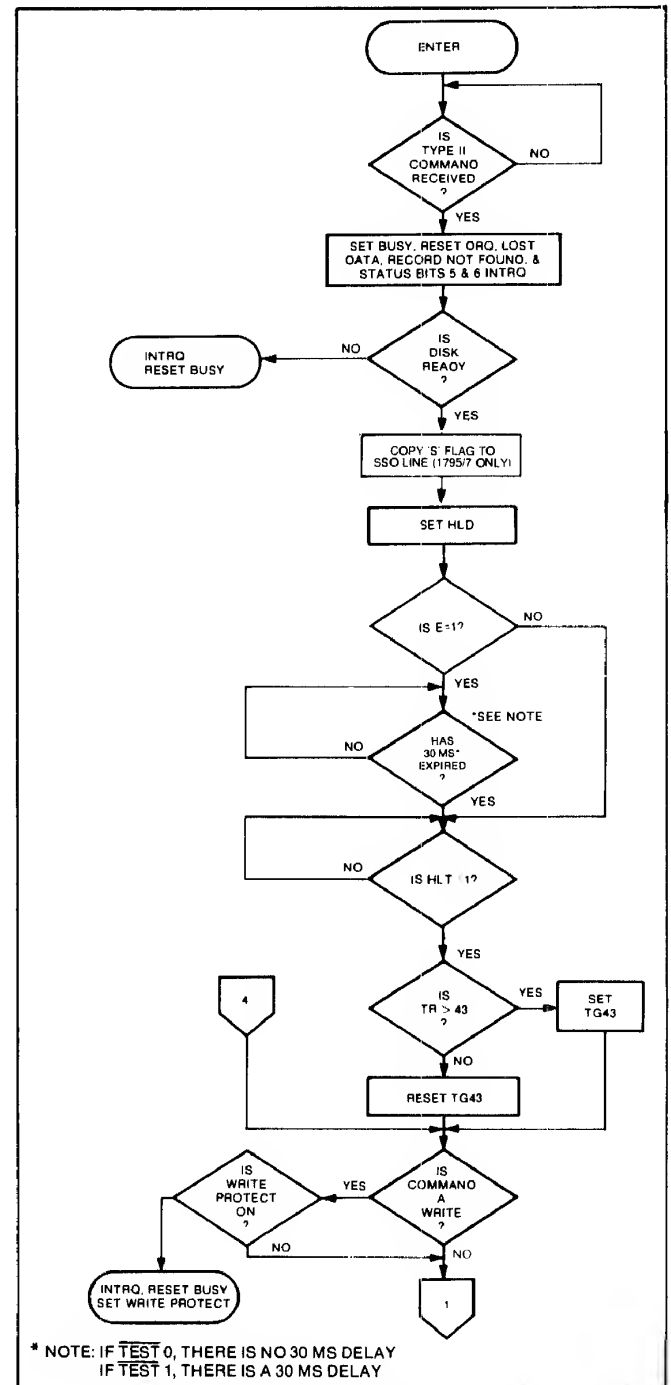

Upon receipt of this command, the FD176X issues one stepping pulse in the direction towards track 80. If the U flag is on, the Track Register is incremented by one. After a delay determined by the r1r0 field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

**TYPE I COMMAND FLOW****STEP-OUT**

Upon receipt of this command, the FD176X issues one stepping pulse in the direction towards track 0. If the U flag is on, the Track Register is decremented by one. After a delay determined by the r1r0 field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

EXCEPTIONS

On the 1765/7 devices, the SSO output is not affected during Type 1 commands, and an internal side compare does not take place when the (V) Verify Flag is on.

**TYPE II COMMAND**

TYPE II COMMANDS

The Type II Commands are the Read Sector and Write Sector commands. Prior to loading the Type II Command into the Command Register, the computer must load the Sector Register with the desired sector number. Upon receipt of the Type II command, the busy status Bit is set. If the E flag = 1 (this is the normal case) HLD is made active and HLT is sampled after a 30 msec delay. If the E flag is 0, the head is loaded and HLT sampled with no 30 msec delay. The ID field and Data Field format are shown on page 16.

When an ID field is located on the disk, the FD176X compares the Track Number on the ID field with the Track Register. If there is not a match, the next encountered ID field is read and a comparison is again made. If there was a match, the Sector Number of the ID field is compared with the Sector Register. If there is not a Sector match, the next encountered ID field is read off the disk and comparisons again made. If the ID field CRC is correct, the data field is then located and will be either written into, or read from depending upon the command. The FD176X must find an ID field with a Track number, Sector number, side number, and CRC within four revolutions of the disk; otherwise, the Record not found status bit is set (Status bit 3) and the command is terminated with an interrupt.

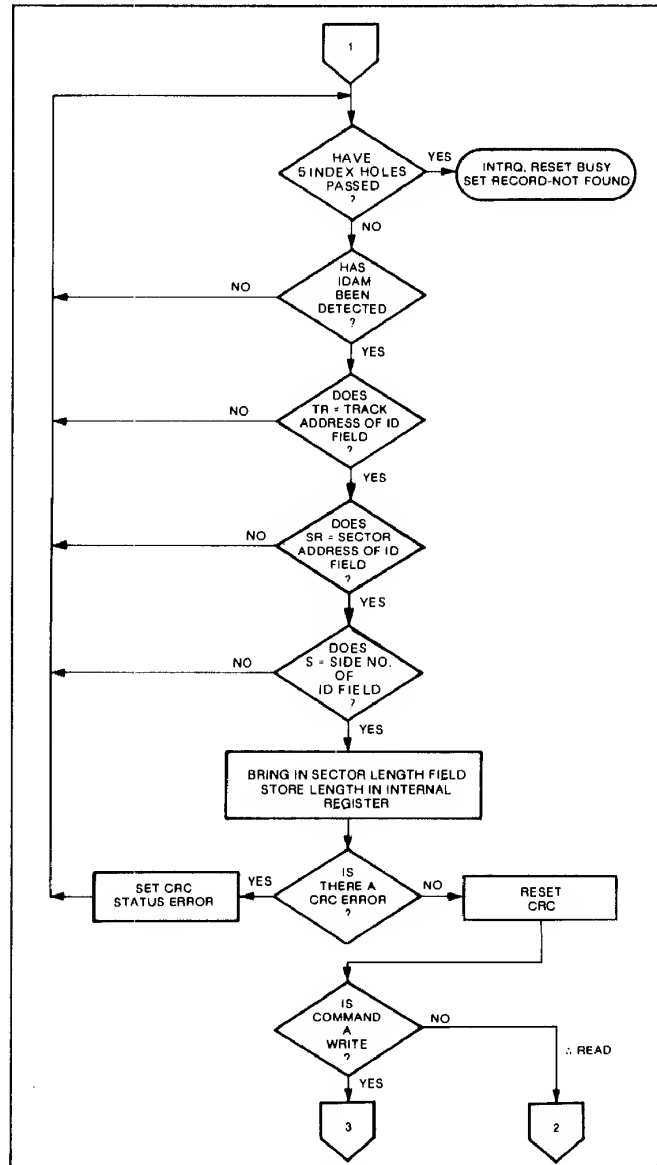

Each of the Type II Commands contains an (m) flag which determines if multiple records (sectors) are to be read or written, depending upon the command. If $m = 0$, a single sector is read or written and an interrupt is generated at the completion of the command. If $m = 1$, multiple records are read or written with the sector register internally updated so that an address verification can occur on the next record. The FD176X will continue to read or write multiple records and update the sector register in numerical ascending sequence until the sector register exceeds the number of sectors on the track or until the Force Interrupt command is loaded into the Command Register, which terminates the command and generates an interrupt.

For example: If the FD176X is instructed to read sector 27 and there are only 26 on the track, the sector register exceeds the number available. The FD176X will search for 5 disk revolutions, interrupt out, reset busy, and set the record not found status bit.

The Type II commands for 1761-63 also contain side select compare flags. When $C = 0$ (Bit 1) no side comparison is made. When $C = 1$, the LSB of the side number is read off the ID Field of the disk and compared with the contents of the (S) flag (Bit 3). If the S flag compares with the side number recorded in the ID field, the FD176X continues with the ID search. If a comparison is not made within 5 index pulses, the interrupt line is made active and the Record-Not-Found status bit is set.

The Type II and III commands for the 1765-67 contain a side select flag (Bit 1). When $U = 0$, SSO is updated to 0. Similarly, $U = 1$ updates SSO to 1. The chip compares the SSO to the ID field. If they do not compare within 5 revolutions the interrupt line is made active and the RNF status bit is set.

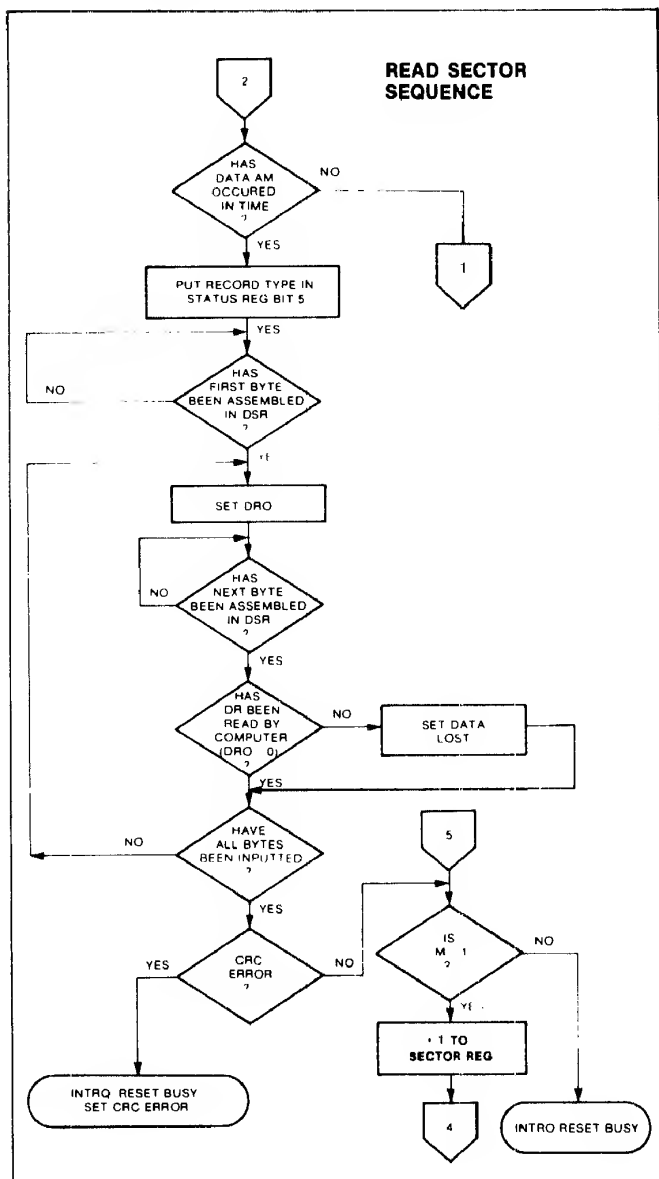

The 1765/7 READ SECTOR and WRITE SECTOR commands include a 'L' flag. The 'L' flag, in conjunction with the sector length byte of the ID Field, allows different byte lengths to be implemented in each sector. For IBM compatibility, the 'L' flag should be set to a one.

TYPE II COMMAND

READ SECTOR

Upon receipt of the Read Sector command, the head is loaded, the Busy status bit set, and when an ID field is encountered that has the correct track number, correct sector number, correct side number, and correct CRC, the data field is presented to the computer. The Data Address Mark of the data field must be found within 30 bytes in single density and 43 bytes in double density of the last ID field CRC byte; if not, the ID field is searched for and verified again followed by the Data Address Mark search. If after 5 revolutions the DAM cannot be found, the Record Not Found status bit is set and the operation is terminated.

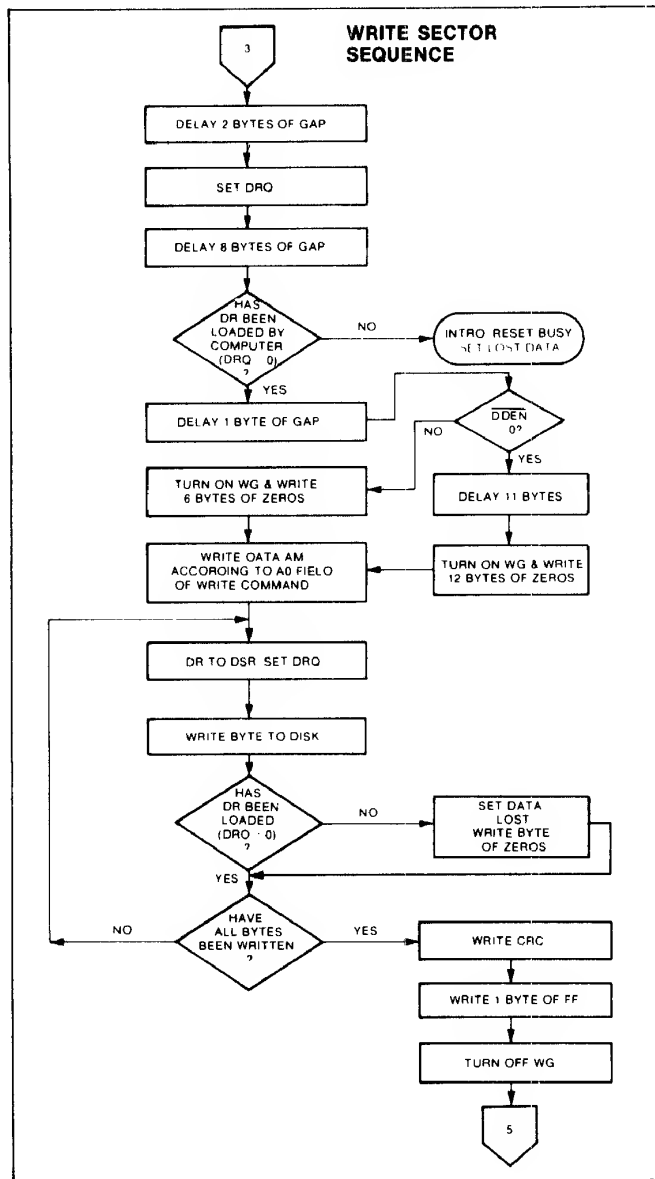

TYPE II COMMAND

When the first character or byte of the data field has been shifted through the DSR, it is transferred to the DR, and DRQ is generated. When the next byte is accumulated in the DSR, it is transferred to the DR and another DRQ is generated. If the Computer has not read the previous contents of the DR before a new character is transferred that character is lost and the Lost Data Status bit is set. This sequence continues until the complete data field has been inputted to the computer. If there is a CRC error at the end of the data field, the CRC error status bit is set, and the command is terminated (even if it is a multiple record command).

At the end of the Read operation, the type of Data Address Mark encountered in the data field is recorded in the Status Register (Bit 5) as shown below:

**STATUS
BIT 5**

1	Deleted Data Mark
0	Data Mark

TYPE II COMMAND

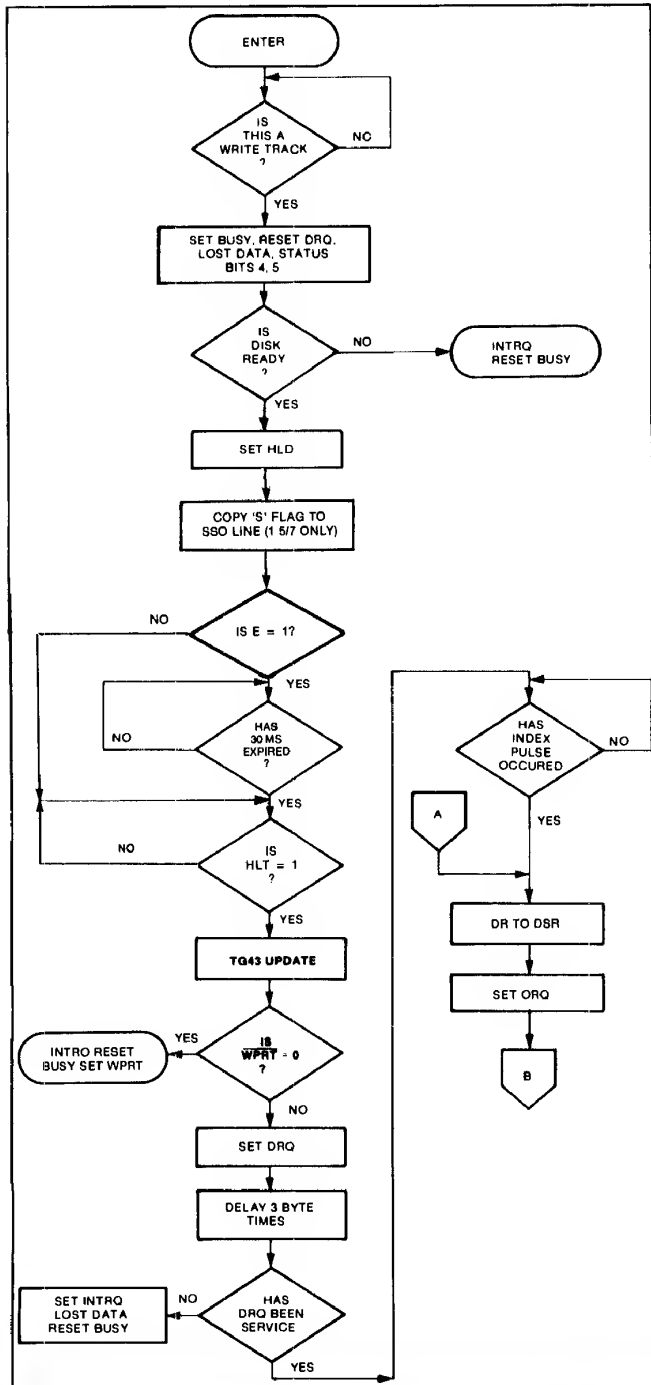

WRITE SECTOR

Upon receipt of the Write Sector command, the head is loaded (HLD active) and the Busy status bit is set. When an ID field is encountered that has the correct track number, correct sector number, correct side number, and correct CRC, a DRQ is generated. The FD176X counts off 11 bytes in single density and 22 bytes in double density from the CRC field and the Write Gate (WG) output is made active if the DRQ is serviced (i.e., the DR has been loaded by the computer). If DRQ has not been serviced, the command is terminated and the Lost Data status bit is set. If the DRQ has been serviced, the WG is made active and six bytes of zeroes in single density and 12 bytes in double density are then written on the disk. At this time the Data Address Mark is then written on the disk as determined by the a0 field of the command as shown below:

a0	Data Address Mark (Bit 0)
1	Deleted Data Mark
0	Data Mark

The FD176X then writes the data field and generates DRQ's to the computer. If the DRQ is not serviced in time for continuous writing the Lost Data Status Bit is set and a byte of zeroes is written on the disk.* The command is not terminated. After the last data byte has been written on the disk, the two-byte CRC is computed internally and written on the disk followed by one byte of logic ones in FM or in MFM. The WG output is then deactivated. For a 1 MHz clock the INTRQ will set 16 to 24 μ sec after the last CRC byte is written.

*If partial sectors are to be written, the proper method is to write the data and fill the balance of the sector with zeroes. Do not let the chip supply the filler by not servicing the DRQs. Doing this will mask any errors by the lost data status and the CRC's may be incorrect.

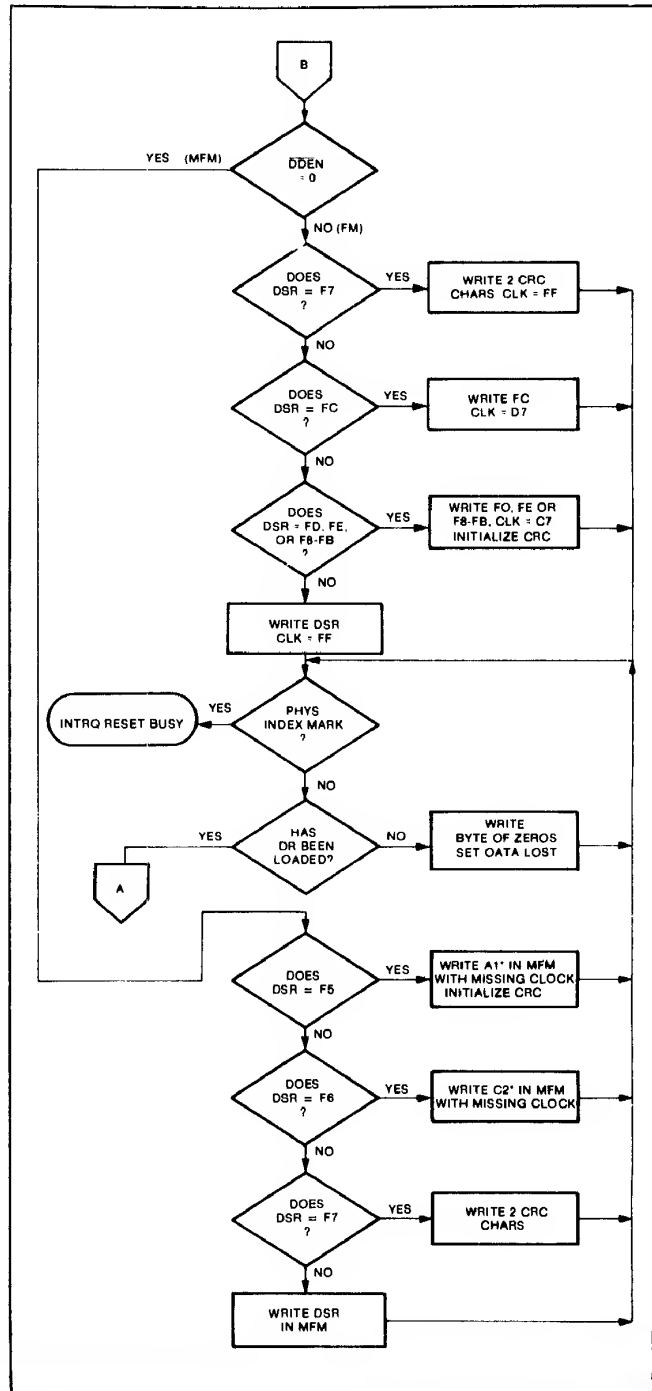

TYPE III COMMANDS

READ ADDRESS

Upon receipt of the Read Address command, the head is loaded and the Busy Status Bit is set. The next encountered ID field is then read in from the disk, and the six data bytes of the ID field are assembled and transferred to the DR, and a DRQ is generated for each byte. The six bytes of the ID field are shown below:

TRACK ADDR	SIDE NUMBER	SECTOR ADDRESS	SECTOR LENGTH	CRC 1	CRC 2
1	2	3	4	5	6

Although the CRC characters are transferred to the computer, the FD176X checks for validity and the CRC error status bit is set if there is a CRC error. The Track Address of the ID field is written into the sector register so that a comparison can be made by the user. At the end of the operation an interrupt is generated and the Busy Status is reset.

READ TRACK

Upon receipt of the READ track command, the head is loaded, and the Busy Status bit is set. Reading starts with the leading edge of the first encountered index pulse and continues until the next index pulse. All Gap, Header, and data bytes are assembled and transferred to the data register and DRQ's are generated for each byte. The accumulation of bytes is synchronized to each address mark encountered. An interrupt is generated at the completion of the command.

This command has several characteristics which make it suitable for diagnostic purposes. They are: the Read Gate is not activated during the command; no CRC checking is performed; gap information is included in the data stream; the internal side compare is not performed; and the address mark detector is on for the duration of the command. Because the A.M. detector is always on, write splices or noise may cause the chip to look for an A.M. If an address mark does not appear on schedule the Lost Data status flag is set.

The ID A.M., ID field, ID CRC bytes, DAM, Data, and Data CRC Bytes for each sector will be correct. The Gap Bytes may be read incorrectly during write-splice time because of synchronization.

WRITE TRACK FORMATTING THE DISK

(Refer to section on Type III commands for flow diagrams.)

Formatting the disk is a relatively simple task when operating programmed I/O or when operating under DMA with a large amount of memory. Data and gap information must be provided at the computer interface. Formatting the disk is accomplished by positioning the R/W head over the desired track number and issuing the Write Track command.

Upon receipt of the Write Track command, the head is

loaded and the Busy Status bit is set. Writing starts with the leading edge of the first encountered index pulse and continues until the next index pulse, at which time the interrupt is activated. The Data Request is activated immediately upon receiving the command, but writing will not start until after the first byte has been loaded into the Data Register. If the DR has not been loaded by the time the index pulse is encountered the operation is terminated making the device Not Busy, the Lost Data Status Bit is set, and the Interrupt is activated. If a byte is not present in the DR when needed, a byte of zeroes is substituted. See note on page 12.

This sequence continues from one index mark to the next index mark. Normally, whatever data pattern appears in the data register is written on the disk with a normal clock pattern. However, if the FD176X detects a data pattern of F5 thru FE in the data register, this is interpreted as data address marks with missing clocks or CRC generation.

The CRC generator is initialized when any data byte from F8 to FE is about to be transferred from the DR to the DSR in FM or by receipt of F5 in MFM. An F7 pattern will generate two CRC characters in FM or MFM. As a consequence, the patterns F5 thru FE must not appear in the gaps, data fields, or ID fields. Also, CRC's must be generated by an F7 pattern.

Disks may be formatted in IBM 3740 or System 34 formats with sector lengths of 128, 256, 512, or 1024 bytes.

TYPE IV COMMANDS

The Forced Interrupt command is generally used to terminate a multiple sector read or write command or to insure Type I status in the status register. This command can be loaded into the command register at any time. If there is a current command under execution (busy status bit set) the command will be terminated and the busy status bit reset.

The lower four bits of the command determine the conditional interrupt as follows:

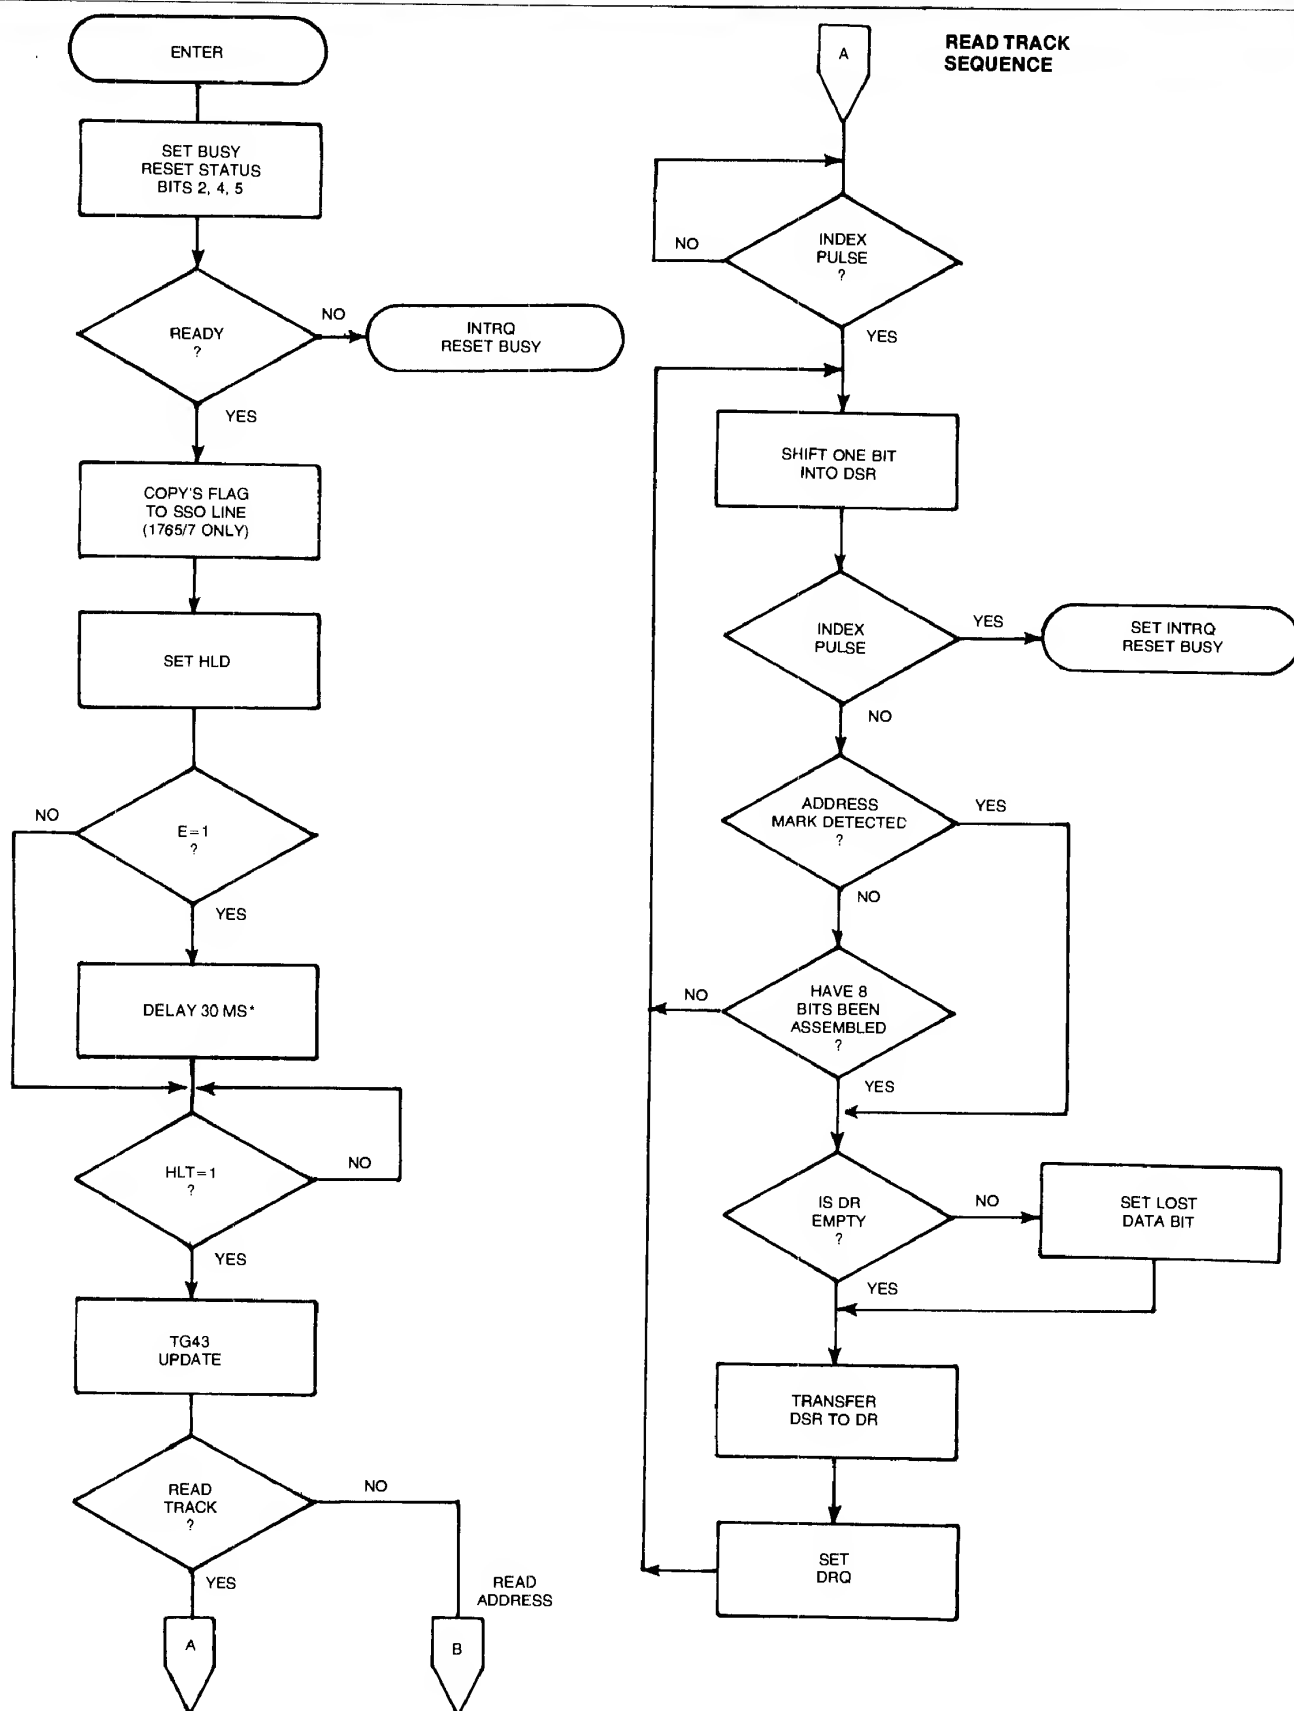

- I0 = Not-Ready to Ready Transition
- I1 = Ready to Not-Ready Transition
- I2 = Every Index Pulse
- I3 = Immediate Interrupt

CONTROL BYTES FOR INITIALIZATION

DATA PATTERN IN DR (HEX)	FD176X INTERPRETATION IN FM (DDEN = 1)	FD176X INTERPRETATION IN MFM (DDEN = 0)
00 thru F4	Write 00 thru F4 with CLK = FF	Write 00 thru F4, in MFM
F5	Not Allowed	Write A1* in MFM, Preset CRC
F6	Not Allowed	Write C2** in MFM
F7	Generate 2 CRC bytes	Generate 2 CRC bytes
F8 thru FB	Write F8 thru FB, Clk = C7, Preset CRC	Write F8 thru FB, in MFM
FC	Write FC with Clk = D7	Write FC in MFM
FD	Write FD with Clk = FF	Write FD in MFM
FE	Write FE, Clk = C7, Preset CRC	Write FE in MFM
FF	Write FF with Clk = FF	Write FF in MFM

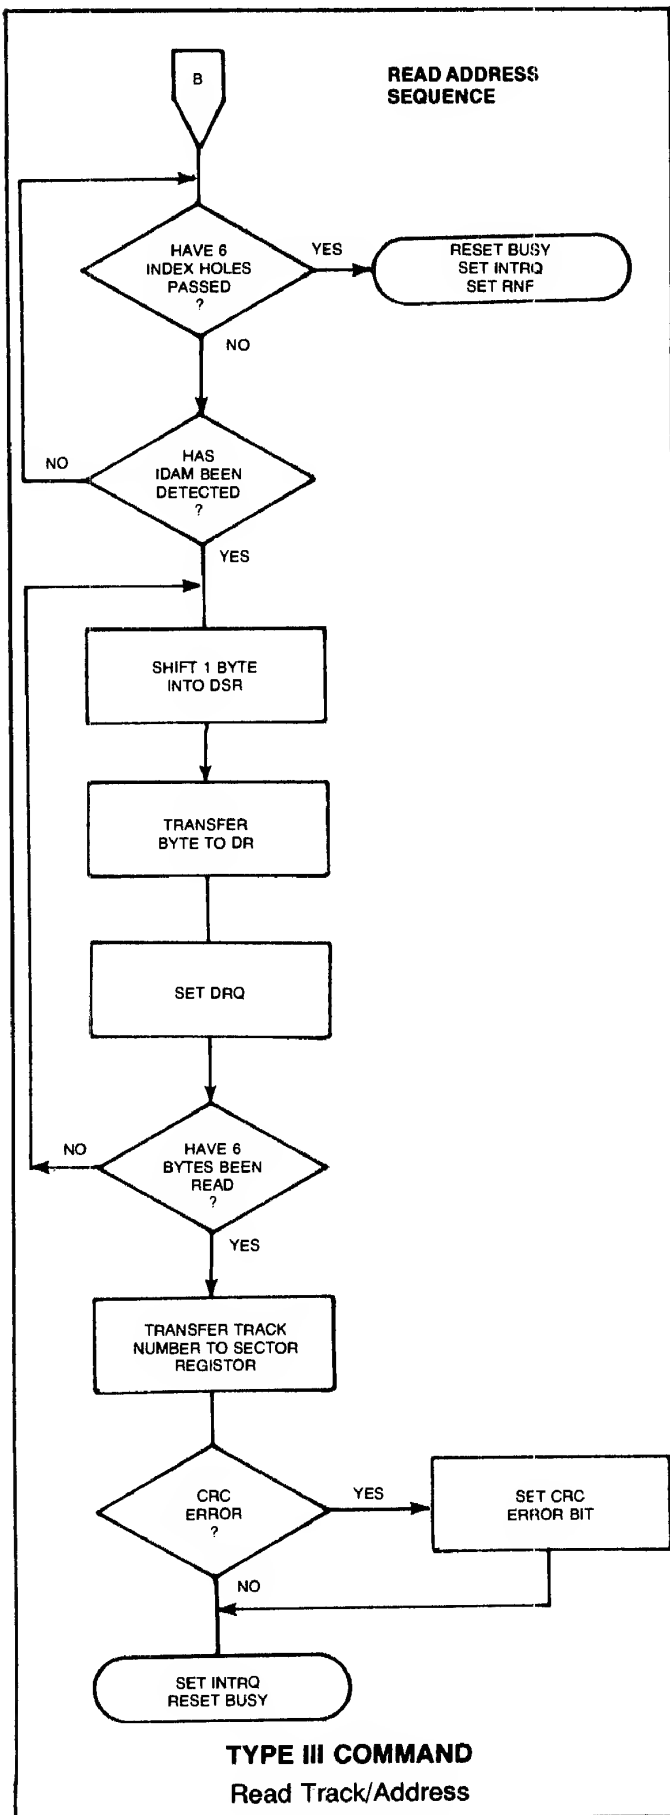

*Missing clock transition between bits 4 and 5

**Missing clock transition between bits 3 & 4

READ TRACK
SEQUENCE*If TEST = ϕ , NO DELAY

If TEST = 1, 30 MS DELAY

TYPE III COMMAND
Read Track/Address

The conditional interrupt is enabled when the corresponding bit positions of the command (I3 - I0) are set to a 1. Then, when the condition for interrupt is met, the INTRQ line will go high signifying that the condition specified has occurred. If I3 - I0 are all set to zero (HEX D0), no interrupt will occur but any command presently under execution will be immediately terminated. When using the immediate interrupt condition (I3 = 1) an interrupt will be immediately generated and the current command terminated. Reading the status or writing to the command register will not automatically clear the interrupt. The HEX D0 is the only command that will enable the immediate interrupt (HEX D8) to clear on a subsequent load command register or read status register operation. Follow a HEX D8 with D0 command.

Wait 16 micro sec (double density) or 32 micro sec (single density) before issuing a new command after issuing a forced interrupt. Loading a new command sooner than this will nullify the forced interrupt.

Forced interrupt stops any command at the end of an internal micro-instruction and generates INTRQ when the specified condition is met. Forced interrupt will wait until ALU operations in progress are complete (CRC calculations, compares, etc.).

More than one condition may be set at a time. If for example, the READY TO NOT-READY condition (I1 = 1) and the Every Index Pulse (I2 = 1) are both set, the resultant command would be HEX "DA". The "OR" function is performed so that either a READY TO NOT-READY or the next Index Pulse will cause an interrupt condition.

STATUS REGISTER

Upon receipt of any command, except the Force Interrupt command, the Busy Status bit is set and the rest of the status bits are updated or cleared for the new command. If the Force Interrupt Command is received when there is a current command under execution, the Busy status bit is reset, and the rest of the status bits are unchanged. If the Force Interrupt command is received when there is not a current command under execution, the Busy Status bit is reset and the rest of the status bits are updated or cleared. In this case, Status reflects the Type I commands.

The user has the option of reading the status register through program control or using the DRQ line with DMA or interrupt methods. When the Data register is read the DRQ bit in the status register and the DRQ line are automatically reset. A write to the Data register also causes both DRQ's to reset.

The busy bit in the status may be monitored with a user program to determine when a command is complete, in lieu of using the INTRQ line. When using the INTRQ, a busy status check is not recommended because a read of the status register to determine the condition of busy will reset the INTRQ line.

The format of the Status Register is shown below:

(BITS)							
7	6	5	4	3	2	1	0
S7	S6	S5	S4	S3	S2	S1	S0

Status varies according to the type of command executed as shown in Table 4.

Because of internal sync cycles, certain time delays must be observed when operating under programmed I/O. They are:

Operation	Next Operation	Delay Req'd.	
		FM	MFM
Write to Command Reg.	Read Busy Bit (Status Bit 0)	24 μ s	12 μ s
Write to Command Reg.	Read Status Bits 1-7	56 μ s	28 μ s
Write Any Register	Read From Diff. Register	0	0

RECOMMENDED — 128 BYTES/SECTOR

Shown below is the recommended single-density format with 128 bytes/sector. In order to format a diskette, the user must issue the Write Track command, and load the data register with the following values. For every byte to be written, there is one Data Request.

NUMBER OF BYTES	HEX VALUE OF BYTE WRITTEN
40	FF (or 00) ¹
6	00
1	FE (ID Address Mark)
1	Track Number
1	Side Number (00 or 01)
1	Sector Number (1 thru 1A)
1	00 (Sector Length)
* 1	F7 (2 CRC's written)
11	FF (or 00) ¹
6	00
1	FB (Data Address Mark)
128	Data (IBM uses E5)
1	F7 (2 CRC's written)
10	FF (or 00) ¹
369**	FF (or 00) ¹

*Write bracketed field 16 times

**Continue writing until FD176X interrupts out.
Approx. 324 bytes.

1-Optional '00' on 1765/7 only.

256 BYTES/SECTOR

Shown below is the recommended dual-density format with 256 bytes/sector. In order to format a diskette the user must issue the Write Track command and load the data register with the following values. For every byte to be written, there is one data request.

NUMBER OF BYTES	HEX VALUE OF BYTE WRITTEN
60	4E
12	00
3	F5 (Writes A1)
1	FE (ID Address Mark)
1	Track Number (0 thru 4C)
1	Side Number (0 or 1)
1	Sector Number (1 thru 1A)
1	01 (Sector Length)
* 1	F7 (2 CRCs written)
22	4E
12	00
3	F5 (Writes A1)
1	FB (Data Address Mark)
256	DATA
1	F7 (2 CRCs written)
24	4E
718**	4E

*Write bracketed field 16 times

**Continue writing until FD176X interrupts out.
Approx. 668 bytes.

1. NON-STANDARD FORMATS

Variations in the recommended formats are possible to a limited extent if the following requirements are met:

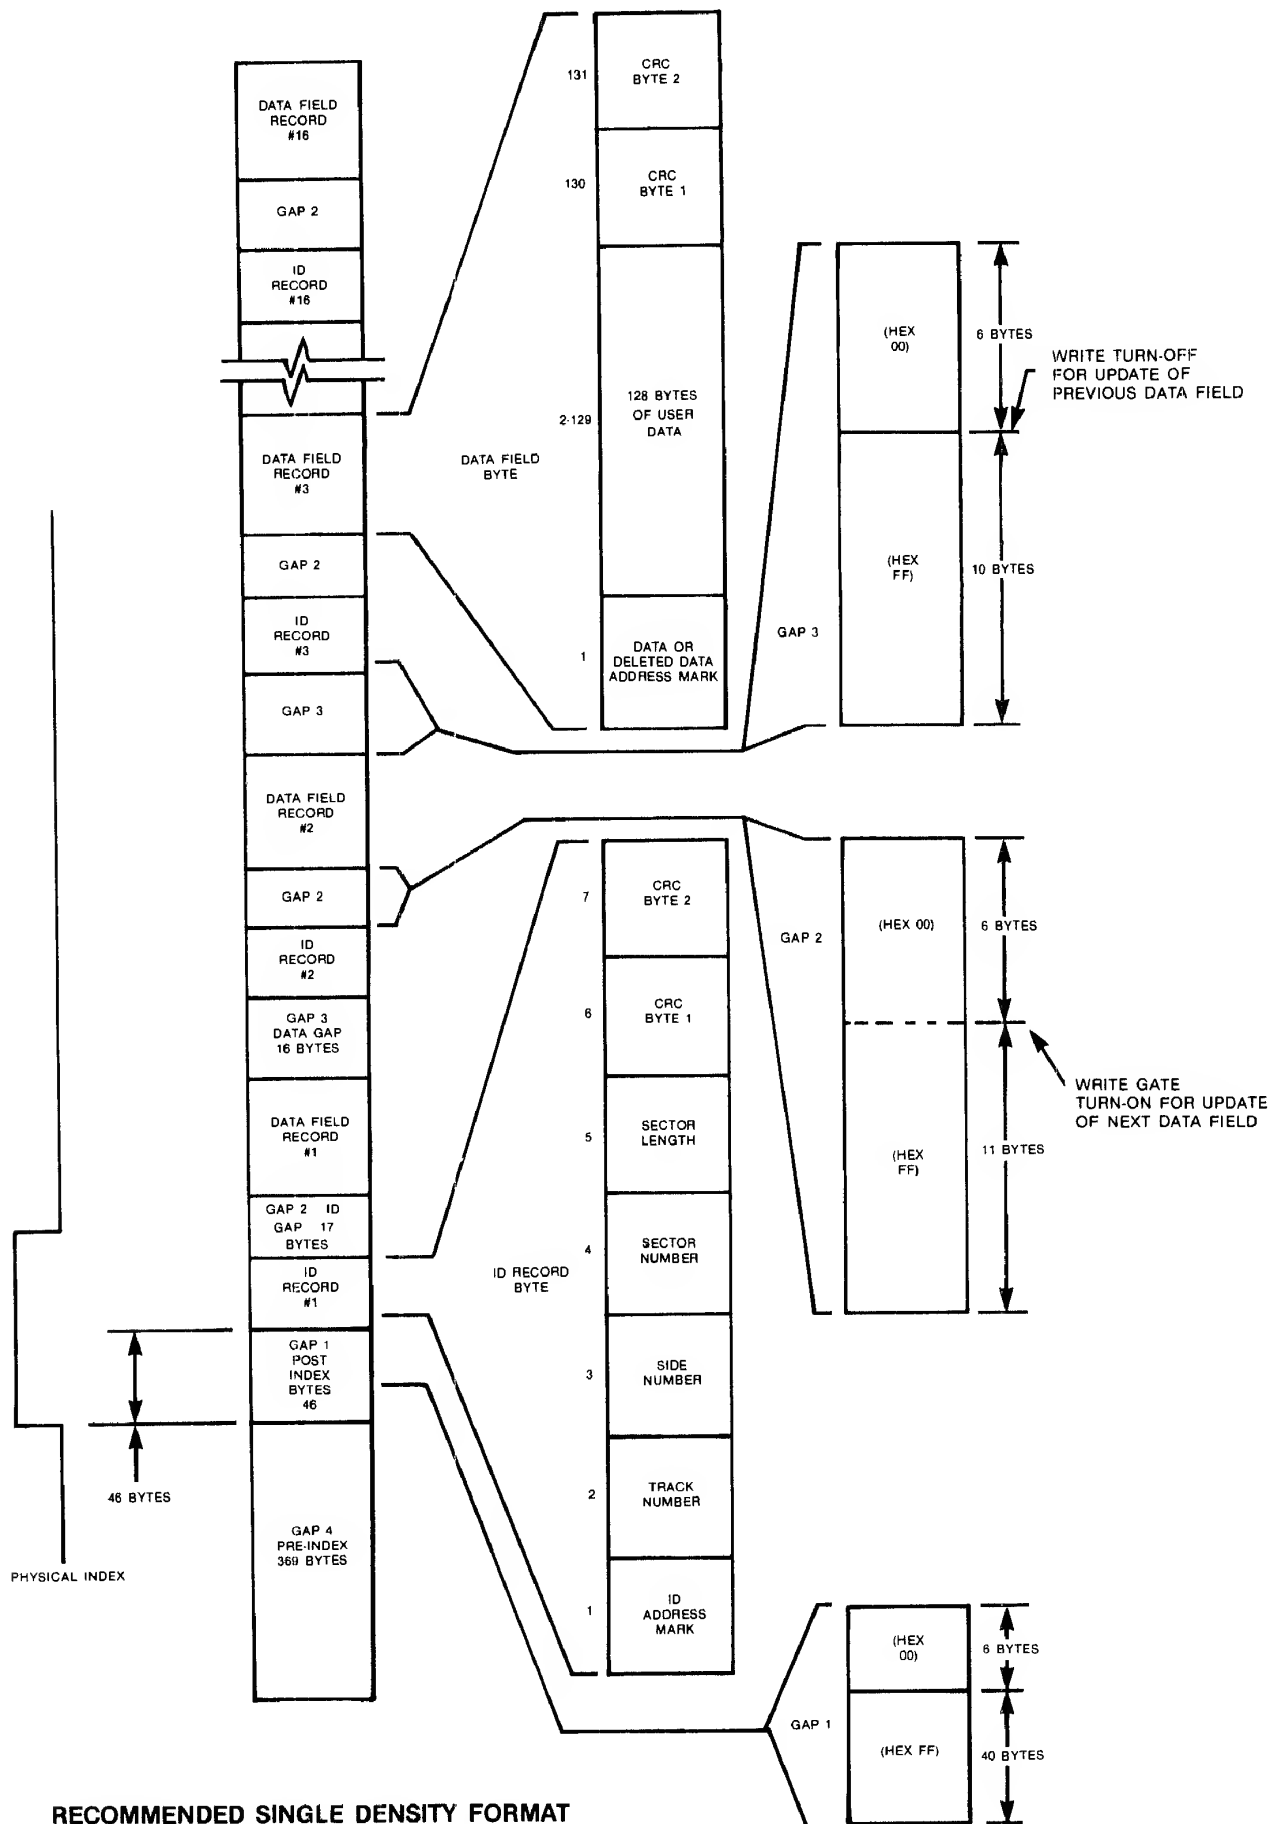

- 1) Sector size must be 128, 256, 512 or 1024 bytes.
- 2) Gap 2 cannot be varied from the recommended format.
- 3) 3 bytes of A1 must be used in MFM.

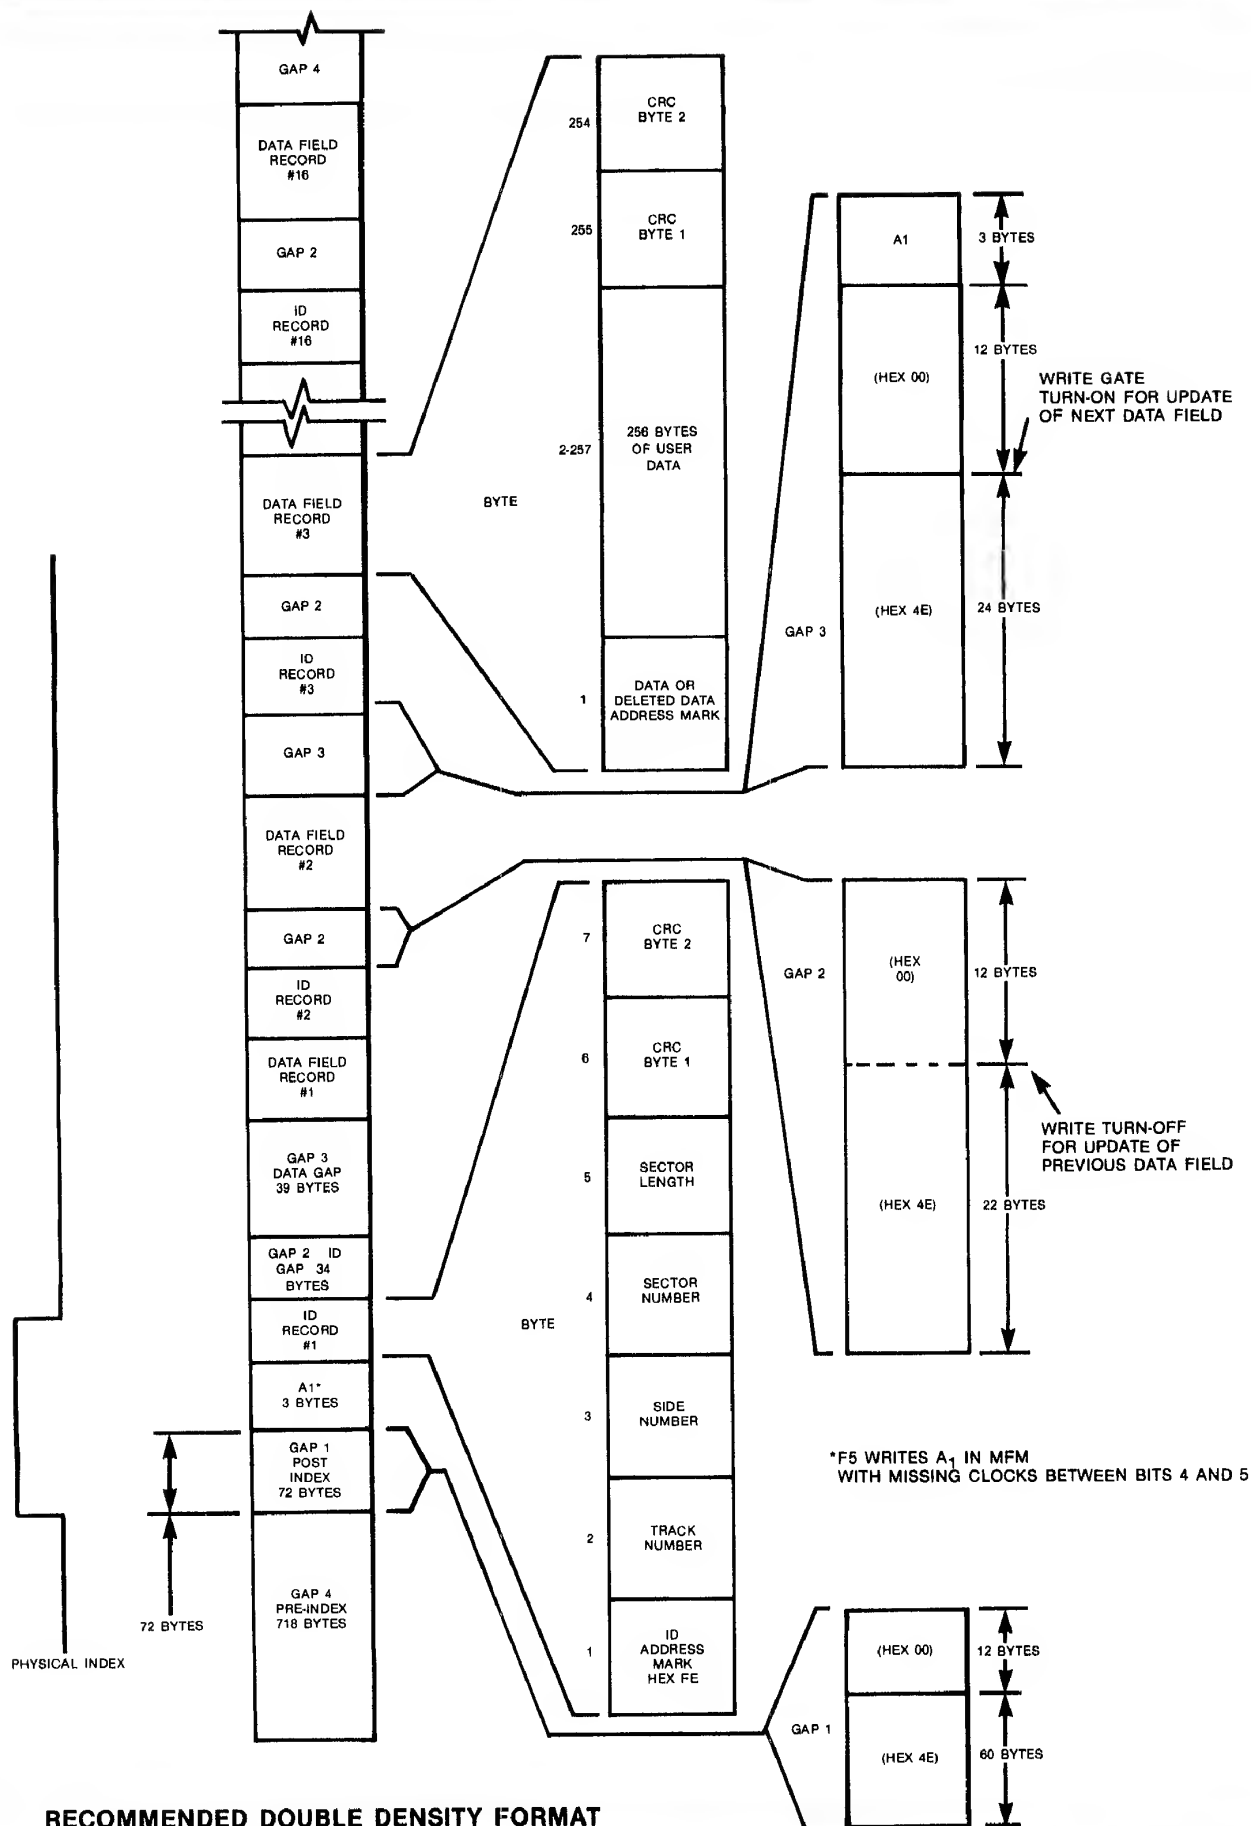

In addition, the Index Address Mark is not required for operation by the FD176X. Gap 1, 3, and 4 lengths can be as short as 2 bytes for FD176X operation, however PLL lock up time, motor speed variation, write-splice area, etc. will add more bytes to each gap to achieve proper operation. It is recommended that the recommended format be used for highest system reliability.

	FM	MFM
Gap I	16 bytes FF	32 bytes 4E
Gap II	11 bytes FF	22 bytes 4E
*	6 bytes 00	12 bytes 00
*		3 bytes A1
Gap III**	10 bytes FF 4 bytes 00	24 bytes 4E 8 bytes 00 3 bytes A1
Gap IV	16 bytes FF	16 bytes 4E

*Byte counts must be exact.

**Byte counts are minimum, except exactly 3 bytes of A1 must be written.

MISCELLANEOUS TIMING

*FROM STEP RATE TABLE

NOTES:

1. Pulse width on RAW READ (Pin 27) is normally 100-300 ns. However, pulse may be any width pulse is entirely within window. If pulse occurs in both windows, then pulse width must be less than 600 ns for MFM at CLK = 1 MHz and 1200 ns for FM at 1 MHz.
2. tbc should be 4 μ s, nominal in MFM and 8 μ s nominal in FM.
3. RCLK may be high or low during RAW READ (Polarity is unimportant).
4. All timing readings at $V_{OL} = .8V$ & $V_{OH} = 2.0V$.

Table 4. STATUS REGISTER SUMMARY

BIT	ALL TYPE I COMMANDS	READ ADDRESS	READ SECTOR	READ TRACK	WRITE SECTOR	WRITE TRACK
S7	NOT READY	NOT READY	NOT READY	NOT READY	NOT READY	NOT READY
S6	WRITE PROTECT	0	0	0	WRITE PROTECT	WRITE PROTECT
S5	HEAD LOADED	0	RECORD TYPE	0	WRITE FAULT	WRITE FAULT
S4	SEEK ERROR	RNF	RNF	0	RNF	0
S3	CRC ERROR	CRC ERROR	CRC ERROR	0	CRC ERROR	0
S2	TRACK 0	LOST DATA	LOST DATA	LOST DATA	LOST DATA	LOST DATA
S1	INDEX PULSE	DRQ	DRQ	DRQ	DRQ	DRQ
S0	BUSY	BUSY	BUSY	BUSY	BUSY	BUSY

STATUS FOR TYPE I COMMANDS

BIT NAME	MEANING
S7 NOT READY	This bit when set indicates the drive is not ready. When reset it indicates that the drive is ready. This bit is an inverted copy of the Ready input and logically 'ored' with MR.
S6 PROTECTED	When set, indicates Write Protect is activated. This bit is an inverted copy of WRPT input.
S5 HEAD LOADED	When set, it indicates the head is loaded and engaged. This bit is a logical "and" of HLD and HLT signals.
S4 SEEK ERROR	When set, the desired track was not verified. This bit is reset to 0 when updated.
S3 CRC ERROR	CRC encountered in ID field.
S2 TRACK 00	When set, indicates Read/Write head is positioned to Track 0. This bit is an inverted copy of the TROO input.
S1 INDEX	When set, indicates index mark detected from drive. This bit is an inverted copy of the IP input.
S0 BUSY	When set command is in progress. When reset no command is in progress.

STATUS FOR TYPE II AND III COMMANDS

BIT NAME	MEANING
S7 NOT READY	This bit when set indicates the drive is not ready. When reset, it indicates that the drive is ready. This bit is an inverted copy of the Ready input and 'ored' with MR. The Type II and III Commands will not execute unless the drive is ready.
S6 WRITE PROTECT	On Read Record: Not Used. On Read Track: Not Used. On any Write: It indicates a Write Protect. This bit is reset when updated.
S5 RECORD TYPE/ WRITE FAULT	On Read Record: It indicates the record-type code from data field address mark. 1 = Deleted Data Mark. 0 = Data Mark. On any Write: It indicates a Write Fault. This bit is reset when updated.
S4 RECORD NOT FOUND (RNF)	When set, it indicates that the desired track, sector, or side were not found. This bit is reset when updated.
S3 CRC ERROR	If S4 is set, an error is found in one or more ID fields; otherwise it indicates error in data field. This bit is reset when updated.
S2 LOST DATA	When set, it indicates the computer did not respond to DRQ in one byte time. This bit is reset to zero when updated.
S1 DATA REQUEST	This bit is a copy of the DRQ output. When set, it indicates the DR is full on a Read Operation or the DR is empty on a Write operation. This bit is reset to zero when updated.
S0 BUSY	When set, command is under execution. When reset, no command is under execution.

ELECTRICAL CHARACTERISTICS**Absolute Maximum Ratings**

V_{DD} with respect to V_{SS} (ground): +15 to -0.3V

Voltage to any input with respect to V_{SS} = +15 to -0.3V

I_{CC} = 60 MA (35 MA nominal)

I_{DD} = 15 MA (10 MA nominal)

C_{IN} & C_{OUT} = 15 pF max with all pins grounded except one under test.

Operating temperature = 0°C to 70°C

Storage temperature = -55°C to +125°C

OPERATING CHARACTERISTICS (DC)

T_A = 0°C to 70°C, V_{DD} = +12V \pm .6V, V_{SS} = 0V, V_{CC} = +5V \pm .25V

SYMBOL	CHARACTERISTIC	MIN.	MAX.	UNITS	CONDITIONS
I_{IL}	Input Leakage		10	μA	$V_{IN} = V_{DD}^{**}$ $V_{OUT} = V_{DD}$
I_{OL}	Output Leakage		10	μA	
V_{IH}	Input High Voltage	2.6		V	$I_O = -100 \mu A$ $I_O = 1.0 mA$
V_{IL}	Input Low Voltage		0.8	V	
V_{OH}	Output High Voltage	2.8		V	
V_{OL}	Output Low Voltage		0.45	V	
P_D	Power Dissipation		0.6	W	

**Leakage conditions are for input pins without internal pull-up resistors. Pins 22, 23, 33, 36, and 37 have pullup resistors. See Tech Memo #115 for testing purposes.

FD1771-01 Floppy Disk Formatter/Controller

FD1771-01

FEATURES

- SOFT SECTOR FORMAT COMPATIBILITY
- AUTOMATIC TRACK SEEK WITH VERIFICATION
- READ MODE
 - Single/Multiple Sector Write with Automatic Sector Search or Entire Track Read
 - Selectable 128 Byte or Variable Length Sector
- WRITE MODE
 - Single/Multiple Sector Write with Automatic Sector Search
 - Entire Track Write for Diskette Formatting
- PROGRAMMABLE CONTROLS
 - Selectable Track-to-Track Stepping Time
 - Selectable Head Settling and Head Engage Times
 - Selectable Three Phase or Step and Direction and Head Positioning Motor Controls
- SYSTEM COMPATIBILITY
 - Double Buffering of Data 8-Bit Bi-Directional Bus for Data, Control and Status
 - DMA or Programmed Data Transfers
 - All Inputs and Outputs are TTL Compatible

APPLICATIONS

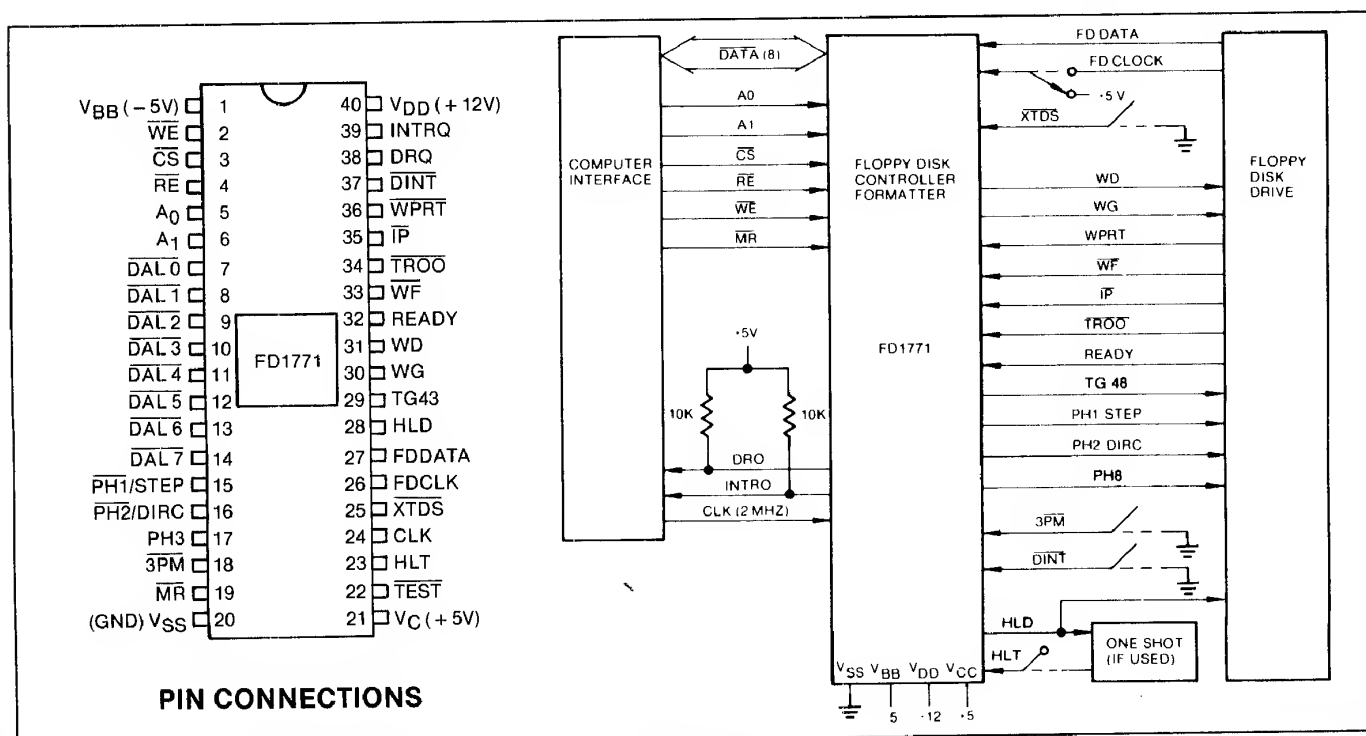

- FLOPPY DISK DRIVE INTERFACE
- SINGLE OR MULTIPLE DRIVE CONTROLLER/FORMATTER
- NEW MINI-FLOPPY CONTROLLER

GENERAL DESCRIPTION

The FD1771 is a MOS/LSI device that performs the functions of a Floppy Disk Controller/Formatter. The device is designed to be included in the disk drive electronics, and contains a flexible interface organization that accommodates the interface signals from most drive manufacturers. The FD1771 is compatible with the IBM 3740 data entry system format.

The processor interface consists of an 8-bit bi-directional bus for data, status, and control word transfers. The FD1771 is set up to operate on a multiplexed bus with other bus-oriented devices.

The FD1771 is fabricated in N-channel Silicon Gate MOS technology and is TTL compatible on all inputs and outputs. The A and B suffixes are for ceramic and plastic packages, respectively.

FD1771 SYSTEM BLOCK DIAGRAM

PIN OUTS

Pin No.	Pin Name	Symbol	Function																				
1 19	Power Supplies <u>MASTER RESET</u>	V_{BB}/NC \overline{MR}	-5V A logic low on this input resets the device and loads "03" into the command register. The Not Ready (Status bit 7) is reset during \overline{MR} ACTIVE. When \overline{MR} is brought to a logic high, a Restore Command is executed, regardless of the state of the Ready signal from the drive.																				
20 21 40		V_{SS} V_{CC} V_{DD}	Ground +5V +12V																				
Computer Interface																							
2	<u>WRITE ENABLE</u>	\overline{WE}	A logic low on this input gates data on the DAL into the selected register when \overline{CS} is low.																				
3	<u>CHIP SELECT</u>	\overline{CS}	A logic low on this input selects the chip and enables computer communication with the device.																				
4	<u>READ ENABLE</u>	\overline{RE}	A logic low on this input controls the placement of data from a selected register on the DAL when \overline{CS} is low.																				
5, 6	REGISTER SELECT LINES	A_0, A_1	These inputs select the register to receive/transfer data on the DAL lines under \overline{RE} and \overline{WE} control: <table> <tr> <th>A_1</th><th>A_0</th><th>\overline{RE}</th><th>\overline{WE}</th></tr> <tr> <td>0</td><td>0</td><td>Status Register</td><td>Command Register</td></tr> <tr> <td>0</td><td>1</td><td>Track Register</td><td>Track Register</td></tr> <tr> <td>1</td><td>0</td><td>Sector Register</td><td>Sector Register</td></tr> <tr> <td>1</td><td>1</td><td>Data Register</td><td>Data Register</td></tr> </table>	A_1	A_0	\overline{RE}	\overline{WE}	0	0	Status Register	Command Register	0	1	Track Register	Track Register	1	0	Sector Register	Sector Register	1	1	Data Register	Data Register
A_1	A_0	\overline{RE}	\overline{WE}																				
0	0	Status Register	Command Register																				
0	1	Track Register	Track Register																				
1	0	Sector Register	Sector Register																				
1	1	Data Register	Data Register																				
7-14	<u>DATA ACCESS LINES</u>	$DAL0-DAL7$	Eight bit inverted bidirectional bus used for transfer of data, control, and status. This bus is a receiver enabled by \overline{WE} or a transmitter enabled by \overline{RE} .																				
24	CLOCK	CLK	This input requires a free-running 2 MHz \pm 1% square wave clock for internal timing reference.																				
38	DATA REQUEST	DRQ	This open drain output indicates that the DR contains assembled data in Read operations, or the DR is empty in Write operations. This signal is reset when serviced by the computer through reading or loading the DR in Read or Write operation, respectively. Use 10K pull-up resistor to +5.																				
39	INTERRUPT REQUEST	INTRQ	This open drain output is set at the completion or termination of any operation and is reset when a new command is loaded into the command register. Use 10K pull-up resistor to +5.																				
Floppy Disk Interface:																							
15	<u>Phase 1/Step</u>	$\overline{PH1}/STEP$	If the $\overline{3PM}$ input is a logic low the three-phase motor control is selected and $\overline{PH1}$, $\overline{PH2}$, and $\overline{PH3}$ outputs form a one active low signal out of three. $\overline{PH1}$ is active low after \overline{MR} . If the $\overline{3PM}$ input is a logic high the step and direction motor control is selected. The step output contains a 4 usec high signal for each step and the direction output is active high when stepping in; active low when stepping out.																				
16	<u>Phase 2/Direction</u>	$\overline{PH2}/DIRC$																					
17	Phase 3	PH3																					
18	<u>3-Phase Motor Select</u>	$\overline{3PM}$																					

Pin No.	Pin Name	Symbol	Function
22	$\overline{\text{TEST}}$	$\overline{\text{TEST}}$	This input is used for testing purposes only and should be tied to +5V or left open by the user.
23	HEAD LOAD TIMING	HLT	The HLT input is sampled after 10 ms. When a logic high is sampled on the HLT input the head is assumed to be engaged.
25	$\overline{\text{EXTERNAL DATA SEPARATION}}$	$\overline{\text{XTDS}}$	A logic low on this input selects external data separation. A logic high or open selects the internal data separator.
26	FLOPPY DISK CLOCK (External Separation)	FDCLOCK	This input receives the externally separated clock when $\overline{\text{XTDS}} = 0$. If $\overline{\text{XTDS}} = 1$, this input should be tied to a logic high.
27	FLOPPY DISK DATA	FDDATA	This input receives the raw read disk data if $\overline{\text{XTDS}} = 1$, or the externally separated data if $\overline{\text{XTDS}} = 0$.
28	HEAD LOAD	HLD	The HLD output controls the loading of the Read-Write head against the media.
29	Track Greater than 43	TG43	This output informs the drive that the Read-Write head is positioned between tracks 44-76. This output is valid only during Read and Write commands.
30	WRITE GATE	WG	This output is made valid when writing is to be performed on the diskette.
31	WRITE DATA	WD	This output contains both clock and data bits of 500 ns duration.
32	Ready	READY	This input indicates disk readiness and is sampled for a logic high before Read or Write commands are performed. If Ready is low, the Read or Write operation is not performed and an interrupt is generated. A Seek operation is performed regardless of the state of Ready. The Ready input appears in inverted format as Status Register bit 7.
33	$\overline{\text{WRITE FAULT}}$	$\overline{\text{WF}}$	This input detects wiring faults indications from the drive. When $\text{WG} = 1$ and $\overline{\text{WF}}$ goes low, the current Write command is terminated and the Write Fault status bit is set. The $\overline{\text{WF}}$ input should be made inactive (high) when WG becomes inactive.
34	$\overline{\text{TRACK 00}}$	$\overline{\text{TR00}}$	This input informs the FD1771 that the Read-Write head is positioned over Track 00 when a logic low.
35	$\overline{\text{INDEX PULSE}}$	$\overline{\text{IP}}$	Input, when low for a minimum of 10 usec, informs the FD1771 when an index mark is encountered on the diskette.
36	$\overline{\text{WRITE PROTECT}}$	$\overline{\text{WPRT}}$	This input is sampled whenever a Write command is received. A logic low terminates the command and sets the Write Protect status bit.
37	$\overline{\text{DISK INITIALIZATION}}$	$\overline{\text{DINT}}$	The input is sampled whenever a Write Track command is received. If $\overline{\text{DINT}} = 0$, the operation is terminated and the Write Protect status bit is set.

ORGANIZATION

The Floppy Disk Formatter block diagram is illustrated on page 4. The primary sections include the parallel processor interface and the Floppy Disk interface.

Data Shift Register: This 8-bit register assembles serial data from the Read Data input (FDDATA) during Read operations and transfers serial data to the Write Data output during Write operations.

Data Register: This 8-bit register is used as a holding register during Disk Read and Write operations. In Disk Read operations the assembled data byte is transferred in parallel to the Data Register from the Data Shift Register. In Disk Write operations information is transferred in parallel from the Data Register to the Data Shift Register.

When executing the Seek command, the Data Register holds the address of the desired Track position. This register can be loaded from the DAL and gated onto the DAL under processor control.

Track Register: This 8-bit register holds the track number of the current Read/Write head position. It is incremented by one every time the head is stepped in (towards track 76) and decremented by one when the head is stepped out (towards track 00). The contents of the register are compared with the recorded track number in the ID field during disk Read, Write, and Verify operations. The Track Register can be

loaded from or transferred to the DAL. This Register should not be loaded when this device is busy.

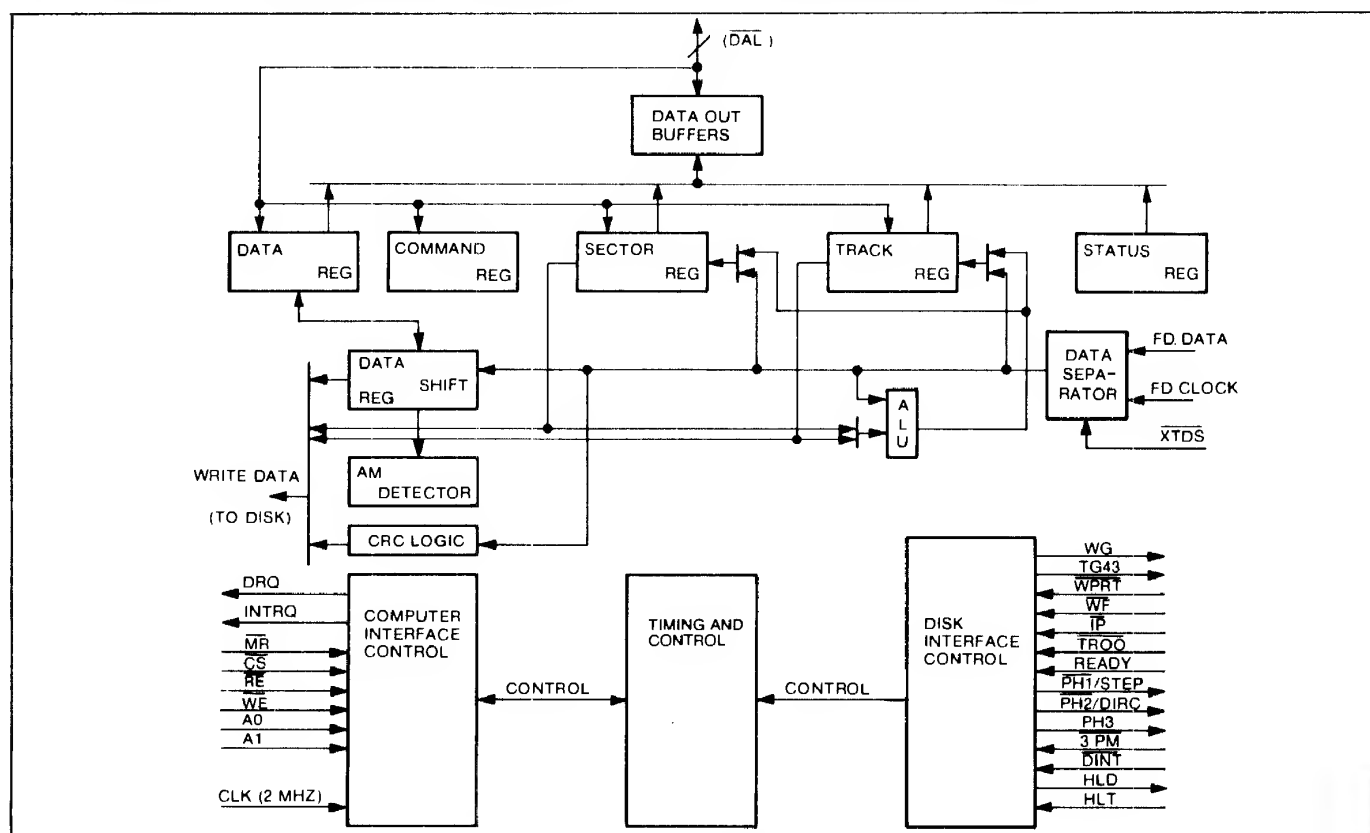

Sector Register (SR): This 8-bit register holds the address of the desired sector position. The contents of the register are compared with the recorded sector number in the ID field during disk Read or Write operations. The Sector Register contents can be loaded from or transferred to the DAL. This register should not be loaded when the device is busy.

Command Register (CR): This 8-bit register holds the command presently being executed. This register should not be loaded when the device is busy unless the execution of the current command is to be overridden. This latter action results in an interrupt. The command register can be loaded from the DAL, but not read onto the DAL.

Status Register (STR): This 8-bit register holds device Status information. The meaning of the Status bits are a function of the contents of the Command Register. This register can be read onto the DAL, but not loaded from the DAL.

CRC Logic: This logic is used to check or to generate the 16-bit Cyclic Redundancy Check (CRC). The polynomial is: $G(x) = x^{16} + x^{12} + x^5 + 1$.

The CRC includes all information starting with the address mark and up to the CRC characters. The CRC register is preset to ones prior to data being shifted through the circuit.

FD1771 BLOCK DIAGRAM

Arithmetic/Logic Unit (ALU): The ALU is a serial comparator, incrementer, and decrements and is used for register modification and comparisons with the disk recorded ID field.

AM Detector: The Address Mark detector is used to detect ID, Data, and Index address marks during Read and Write operations.

Timing and Control: All computer and Floppy Disk Interface controls are generated through this logic. The internal device timing is generated from a 2.0 MHz external crystal clock.

PROCESSOR INTERFACE

The interface to the processor is accomplished through the eight Data Access Lines (DAL) and associated control signals. The DAL are used to transfer Data, Status, and Control words out of, or into the FD1771. The DAL are three-state buffers that are enabled as output drivers when Chip Select (CS) and Read Enable (RE) are active (low logic state) or act as input receivers when CS and Write Enable (WE) are active.

When transfer of data with the Floppy Disk Controller is required by the host processor, the device address is decoded and CS is made low. The least-significant address bits A1 and A0, combined with the signals RE during a Read operation or WE during a Write operation are interpreted as selecting the following registers:

A1-A0	READ (RE)	WRITE (WE)
0 0	Status Register	Command Register
0 1	Track Register	Track Register
1 0	Sector Register	Sector Register
1 1	Data Register	Data Register

During Direct Memory Access (DMA) types of data transfers between the Data Register of the FD1771 and the Processor, the Data Request (DRQ) output is used in Data Transfer control. This signal also appears as status bit 1 during Read and Write operations.

On Disk Read operations the Data Request is activated (set high) when an assembled serial input byte is transferred in parallel to the Data Register. This bit is cleared when the Data Register is read by the processor. If the Data Register is read after one or more characters are lost, by having new data transferred into the register prior to processor readout, the Lost Data bit is set in the Status Register. The Read operation continues until the end of sector is reached.

On Disk Write operations the Data Request is activated when the Data Register transfers its contents to the Data Shift Register, and requires a new data byte. It is reset when the Data Register is loaded with new data by the processor. If new data is not loaded

at the time the next serial byte is required by the Floppy Disk, a byte of zeroes is written on the diskette and the Lost Data bit is set in the Status Register.

The Lost Data bit and certain other bits in the Status Register will activate the interrupt request (INTRQ). The interrupt line is also activated with normal completion or abnormal termination of all controller operations. The INTRQ signal remains active until reset by reading the Status Register to the processor or by the loading of the Command Register. In addition, the INTRQ is generated if a Force Interrupt command condition is met.

FLOPPY DISK INTERFACE

The Floppy Disk interface consists of head positioning controls, write gate controls, and data transfers. A 2.0 MHz $\pm 1\%$ square wave clock is required at the CLK input for internal control timing (may be 1.0 MHz for mini floppy).

HEAD POSITIONING

Four commands cause positioning of the Read-Write head (see Command Section). The period of each positioning step is specified by the r field in bits 1 and 0 of the command word. After the last directional step, an additional 10 milliseconds of head settling time takes place. The four programmable stepping rates are tabulated below.

The rates (shown in Table 1) can be applied to a Three-Phase Motor or a Step-Direction Motor through the device interface. When the $\overline{3PM}$ input is connected to ground, the device operates with a three-phase motor control interface, with one active low signal per phase on the three output signals $\overline{PH1}$, $\overline{PH2}$, and $\overline{PH3}$. The stepping sequence, when stepping in, is Phases 1-2-3-1, and when stepping out, Phases 1-3-2-1. Phase 1 is active low after Master Reset. Note: $\overline{PH3}$ needs an inverter if used.

The Step-Direction Motor Control interface is activated by leaving input $\overline{3PM}$ open or connecting it to +5V. The Phase 1 pin $\overline{PH1}$ becomes a Step pulse of 4 microseconds width. The Phase 2 pin $\overline{PH2}$ becomes a direction control with a high voltage on this pin indicating a Step In, and a low voltage indicating a Step Out. The Direction output is valid a minimum of 24 μs prior to the activation of the Step pulse.

When a Seek, Step or Restore command is executed, an optional verification of Read-Write head position can be performed by setting bit 2 in the command word to a logic 1. The verification operation begins at the end of the 10 millisecond settling time after the head is loaded against the media. The track number from the first encountered ID Field is compared against the contents of the Track Register. If the track numbers compare and the ID Field Cyclic Redundancy Check (CRC) is correct, the verify operation is complete. If track comparison is not

made but the CRC checks, an interrupt is generated, the Seek Error status (Bit 4) is set and the Busy status bit is reset.

Table 1. STEPPING RATES

r_1	r_0	1771-X1 CLK = 2 MHz TEST = 1	1771-X1 CLK = 1 MHz TEST = 1	1771 or -X1 CLK = 2 MHz TEST = 0	1771 or -X1 CLK = 1 MHz TEST = 0
0	0	6ms	12ms	Approx. 400 μ s*	Approx. 800 μ s*
0	1	6ms	12ms		
1	0	10ms	20ms		
1	1	20ms	40ms		

*For exact times consult WDC.

The Head Load (HLD) output controls the movement of the read/write head against the disk for data recording or retrieval. It is activated at the beginning of a Read, Write (E Flag On) or Verify operation, or a Seek or Step operation with the head load bit, h, a logic one remains activated until the third index pulse following the last operation which uses the read/write head. Reading or Writing does not occur until a minimum of 10 msec delay after the HLD signal is made active. If executing the type 2 commands with the E flag off, there is no 10 msec delay and the head is assumed to be engaged. The delay is determined by sampling of the Head Load Timing (HLT) input after 10 msec. A high state input, generated from the Head Load output transition and delayed externally, identifies engagement of the head against the disk. In the Seek and Step commands, the head is loaded at the start of the command execution when the h bit is a logic one. In a verify command the head is loaded after stepping to the destination track on the disk whenever the h bit is a logic zero.

DISK READ OPERATION

The 2.0 MHz external clock provided to the device is internally divided by 4 to form the 500 kHz clock rate for data transfer. When reading data from a diskette this divider is synchronized to transitions of the Read Data (FDDATA) input. When a transition does not occur on the 500 kHz clock active state, the clock divider circuit injects a clock to maintain a continuous 500 kHz data clock. The 500 kHz data clock is further divided by 2 internally to separate the clock and information bits. The divider is phased to the information by the detection of the address mark.

In the internal data read and separation mode the Read Data input toggles from one state to the opposite state for each logic one bit of clock or information. This signal can be derived from the amplified, differentiated, and sliced Read Head signal, or by the output of a flip-flop toggling on the Read Data pulses. This input is sampled by the 2 MHz clock to detect transitions.

The chip can also operate on externally separated

data, as supplied by methods such as Phase Lock loop, One Shots, or variable frequency oscillators. This is accomplished by grounding the External Data Separator ($\overline{\text{XTDS}}$) INPUT. When the Read Data input makes a high-to-low transition, the information input to the FDDATA line is clocked into the Data Shift Register. The assembled 8-bit data from the Data Shift Register are then transferred to the Data Register.

The normal sector length for read or Write operations with the IBM 3740 format is 128 bytes. This format or binary multiples of 128 bytes will be adopted by setting a logic 1 in Bit 3 of the Read and Write commands. Additionally, a variable sector length feature is provided which allows an indicator recorded in the ID Field to control the length of the sector. Variable sector lengths can be read or written in Read or Write commands, respectively, by setting a logic 0 in Bit 3 of the command word. The sector length indicator specifies the number of 16 byte groups or $16 \times N$, where N is equal to 1 to 256 groups. An indicator of all zeroes is interpreted as 256 sixteen byte groups.

DISK WRITE OPERATION

After data is loaded from the processor into the Data Register, and is transferred to the Data Shift Register, data will be shifted serially through the Write Data (WD) output. Interlaced with each bit of data is a positive clock pulse of 0.5 μ sec duration. This signal may be used to externally toggle a flip-flop to control the direction of Write Current flow.

When writing is to take place on the diskette the Write Gate (WG) output is activated, allowing current to flow into the Read/Write head. As a precaution to erroneous writing, the first data byte must be loaded into the Data Register in response to a Data Request from the FD1771 before the Write Gate signal can be activated.

Writing is inhibited when the $\overline{\text{Write Protect}}$ input is a logic low, in which case any Write command is immediately terminated, an interrupt is generated and the Write Protect status bit is set. The $\overline{\text{Write Fault}}$ input, when activated, signifies a writing fault condition detected in disk drive electronics such as failure to detect write current flow when the Write Gate is activated. On detection of this fault the FD1771 terminates the current command, and sets the $\overline{\text{Write Fault}}$ bit (bit 5) in the Status Word. The $\overline{\text{Write Fault}}$ input should be made inactive when the Write Gate output becomes inactive.

Whenever a Read or Write command is received the FD1771 samples the $\overline{\text{READY}}$ input. If this input is logic low the command is not executed and an interrupt is generated. The Seek or Step commands are performed regardless of the state of the $\overline{\text{READY}}$ input.

COMMAND DESCRIPTION

The FD1771 will accept and execute eleven commands. Command words should only be loaded in the Command Register when the Busy status bit is off (status bit 0). The one exception is the Force Interrupt command. Whenever a command is being executed, the Busy status bit is set. When a command is completed, an interrupt is generated and the Busy status bit is reset. The Status Register indicates whether the completed command encountered an error or was fault-free. For ease of discussion, commands are divided into four types. Commands and types are summarized in Table 2.

TYPE 1 COMMANDS

The Type 1 Commands include the RESTORE, SEEK, STEP, STEP-IN, and STEP-OUT commands. Each of the Type 1 Commands contain a rate field (r_0r_1), which determines the stepping motor rate as defined in Table 1, page 4.

The Type 1 Commands contain a head load flag (h) which determines if the head is to be loaded at the beginning of the command. If $h=1$, the head is loaded at the beginning of the command (HLD output is made active). If $h=0$, HLD is deactivated.

Table 2. COMMAND SUMMARY

TYPE	COMMAND	BITS							
		7	6	5	4	3	2	1	0
I	Restore	0	0	0	0	h	V	r_1	r_0
I	Seek	0	0	0	1	h	V	r_1	r_0
I	Step	0	0	1	u	h	V	r_1	r_0
I	Step In	0	1	0	u	h	V	r_1	r_0
I	Step Out	0	1	1	u	h	V	r_1	r_0
II	Read Command	1	0	0	m	b	E	0	0
II	Write Command	1	0	1	m	b	E	a_1	a_0
III	Read Address	1	1	0	0	0	E	0	0
III	Read Track	1	1	1	0	0	1	0	\bar{s}
III	Write Track	1	1	1	1	0	1	0	0
IV	Force Interrupt	1	1	0	1	l_3	l_2	l_1	l_4

Note: Bits shown in TRUE form.

Table 3. FLAG SUMMARY

TYPE I
h = Head Load flag (Bit 3)
h = 1, Load head at beginning
h = 0, Do not load head at beginning
V = Verify flag (Bit 2)
V = 1, Verify on last track
V = 0, No verify
r_1r_0 = Stepping motor rate (Bits 1-0)
Refer to Table 1 for rate summary
u = Update flag (Bit 4)
u = 1, Update Track register
u = 0, No update

Table 4. FLAG SUMMARY

TYPE II
m = Multiple Record flag (Bit 4)
m = 0, Single Record
m = 1, Multiple Records
b = Block length flag (Bit 3)
b = 1, IBM format (128 to 1024 bytes)
b = 0, Non-IBM format (16 to 4096 bytes)
a_1a_0 = Data Address Mark (Bits 1-0)
a_1a_0 = 00, FB (Data Mark)
a_1a_0 = 01, FA (User defined)
a_1a_0 = 10, F9 (User defined)
a_1a_0 = 11, F8 (Deleted Data Mark)

Table 5. FLAG SUMMARY

TYPE III
s = Synchronize flag (Bit 0)
\bar{s} = 0, Synchronize to AM
\bar{s} = 1, Do Not Synchronize to AM
TYPE IV
l_i = Interrupt Condition flags (Bits 3-0)
l_0 = 1, Not Ready to Ready Transition
l_1 = 1, Ready to Not Ready Transition
l_2 = 1, Index Pulse
l_3 = 1, Immediate interrupt
E = Enable HLD and 10 msec Delay
E = 1, Enable HLD, HLT and 10 msec Delay
E = 0, Head is assumed Engaged and there is no 10 msec Delay

Once the head is loaded, the head will remain engaged until the FD1771 receives a command that specifically disengages the head. If the FD1771 does not receive any commands after two revolutions of the disk, the head will be automatically disengaged (HLD made inactive). The Head Load Timing Input is sampled after a 10 ms delay, when reading or writing on the disk is to occur.

The Type 1 Commands also contain a verification (V) flag which determines if a verification operation is to take place on the destination track. If $V=1$, a verification is performed; if $V=0$, no verification is performed.

During verification, the head is loaded and after an internal 10 ms delay, the HLT input is sampled. When HLT is active (logic true), the first encountered ID field is read off the disk. The track address of the ID Field is then compared to the Track Register; if there is a match and a valid ID CRC, the verification is complete, an interrupt is generated and the BUSY status bit is reset. If there is not a match but there is

valid ID CRC, an interrupt is generated, the Seek Error status bit (Status Bit 4) is set and the BUSY status bit is reset. If there is a match but not a valid CRC, the CRC error status bit is set (Status Bit 3), and the next encountered ID Field is read from the disk for the verification operation. If an ID Field with a valid CRC cannot be found after two revolutions of the disk, the FD1771 terminates the operation and sends an interrupt (INTRQ).

The STEP, STEP-IN, and STEP-OUT commands contain an UPDATE flag (U). When U=1, the track register is updated by one for each step. When U=0, the track register is not updated.

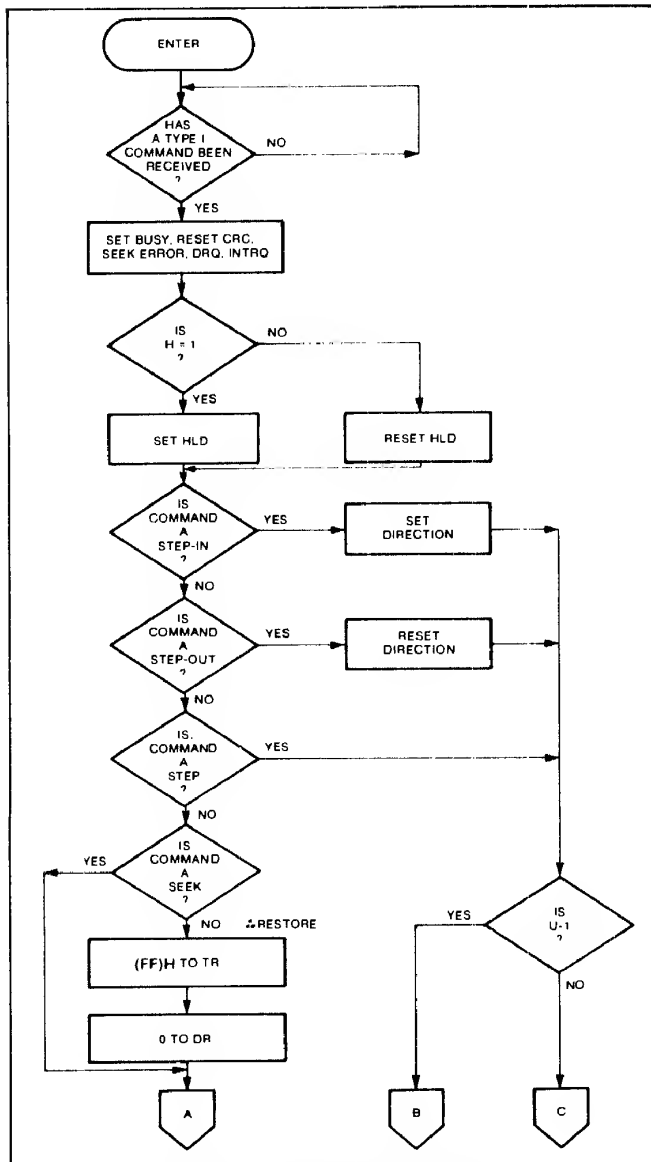

RESTORE (SEEK TRACK 0)

Upon receipt of this command the Track 00 ($\overline{TR00}$) input is sampled. If $\overline{TR00}$ is active low indicating the Read-Write head is positioned over track 0, the Track

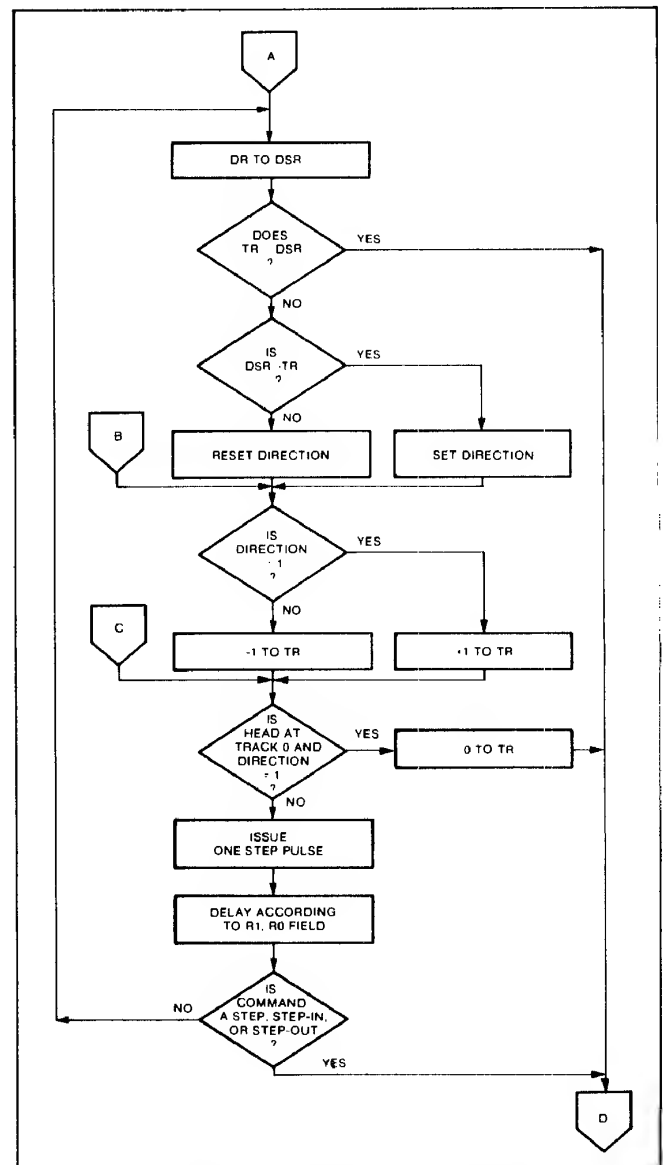

Register is loaded with zeroes and an interrupt is generated. If $\overline{TR00}$ is not active low, stepping pulses (pins 15 to 17) at a rate specified by the r_1r_0 field are issued until the $\overline{TR00}$ input is activated. At this time the TR is loaded with zeroes and an interrupt is generated. If the $\overline{TR00}$ input does not go active low after 255 stepping pulses, the FD1771 terminates operation, interrupts, and sets the Seek error status bit. Note that the RESTORE command is executed when \overline{MR} goes from an active to an inactive state. A verification operation takes place if the V flag is set. The h bit allows the head to be loaded at the start of command.

SEEK

This command assumes that the Track Register contains the track number of the current position of the Read-Write head and the Data Register contains the desired track number. The FD1771 will update the

TYPE I COMMAND FLOW

TYPE I COMMAND FLOW

Track register and issue stepping pulses in the appropriate direction until the contents of the Track register are equal to the contents of the data register (the desired track location). A verification operation takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP

Upon receipt of this command, the FD1771 issues one stepping pulse to the disk drive. The stepping motor direction is the same as in the previous step command. After a delay determined by the r_1r_0 field, a verification takes place if the V flag is on. If the u flag is on, the TR is updated. The h bit allows the head to be loaded at the start of the command. An

interrupt is generated at the completion of the command.

STEP-IN

Upon receipt of this command, the FD1771 issues one stepping pulse in the direction towards track 76. If the u flag is on, the Track Register is incremented by one. After a delay determined by the r_1r_0 field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP-OUT

Upon receipt of this command, the FD1771 issues one stepping pulse in the direction towards track 0. If the u flag is on, the TR is decremented by one. After a delay determined by the r_1r_0 field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

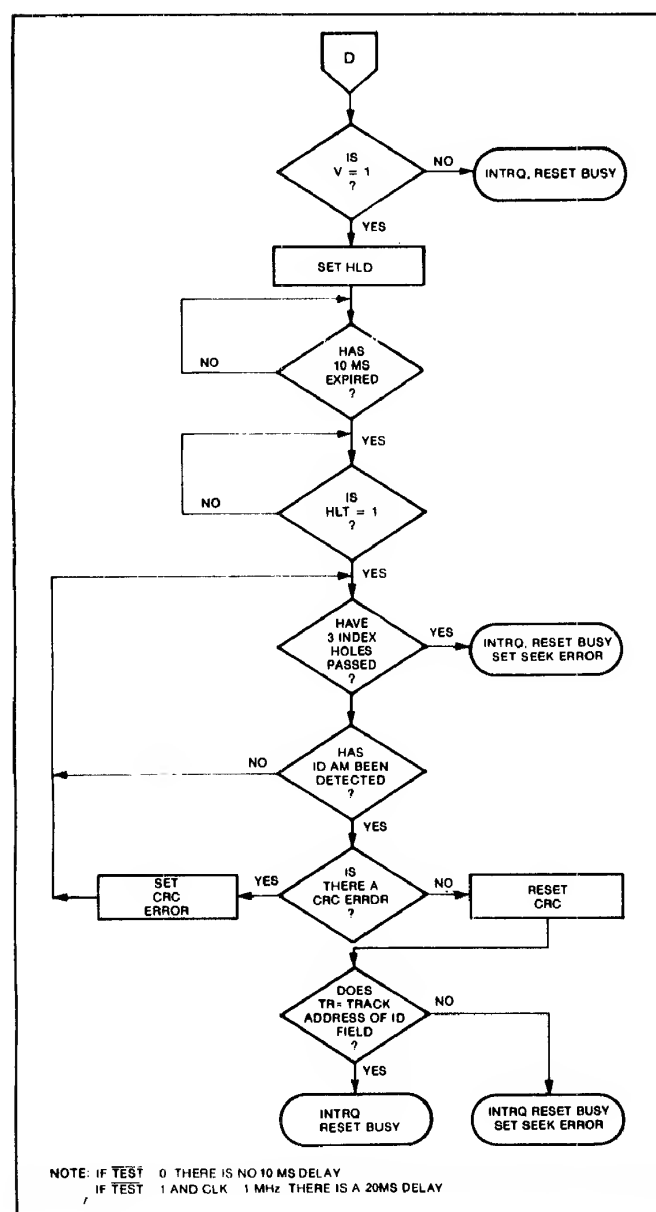

TYPE II COMMANDS

The Type II Commands include the Read Sector(s) and Write Sector(s) commands. Prior to loading the Type II command into the COMMAND REGISTER, the computer must load the Sector Register with the desired sector number. Upon receipt of the Type II command, the Busy status bit is set. If the E flag=1 (this is the normal case), HLD is made active and HLT is sampled after a 10 msec delay. If the E flag is 0, the head is assumed to be engaged and there is no 10 msec delay. The ID field and the Data Field format are shown below.

When an ID field is located on the disk, the FD1771 compares the track number of the ID field with the Track Register. If there is not a match, the next encountered ID field is read and a comparison is again made. If there was a match, the Sector Number of the ID field is compared with the Sector Register. If there is not a Sector match, the next encountered ID field is read off the disk and comparisons again made. If the ID field CRC is correct, the data field is then located and will be either written into, or read from depending on the command. The FD1771 must find an ID field with a track number, Sector number, and CRC within two revolutions of the disk; otherwise, the Record Not Found status bit is set (Status bit 3) and the command is terminated with an interrupt.

Each of the Type II Commands contain a (b) flag which in conjunction with the sector length field contents of the ID determines the length (number of characters) of the Data field.

For IBM 3740 compatibility, the b flag should equal 1. The numbers of bytes in the data field (sector) is then 128×2^n where $n = 0, 1, 2, 3$.

TYPE I COMMAND FLOW

GAP	ID AM	TRACK NUMBER	ZERO	SECTOR NUMBER	SECTOR LENGTH	CRC 1	CRC 2	GAP	DATA AM	DATA FIELD	CRC 1	CRC 2
ID FIELD									DATA FIELD			

IDAM = ID Address Mark — DATA = (FE)₁₆ CLK = (C7)₁₆

Data AM = Data Address Mark — DATA = (F8, F9, FA, or FB), CLK = (C7)₁₆

For b = 1

Sector Length Field (Hex)	Number of Bytes in Sector (Decimal)
00	128
01	256
02	512
03	1024

When the b flag equals zero, the sector length field (n) multiplied by 16 determines the number of bytes in the sector or data field as shown below.

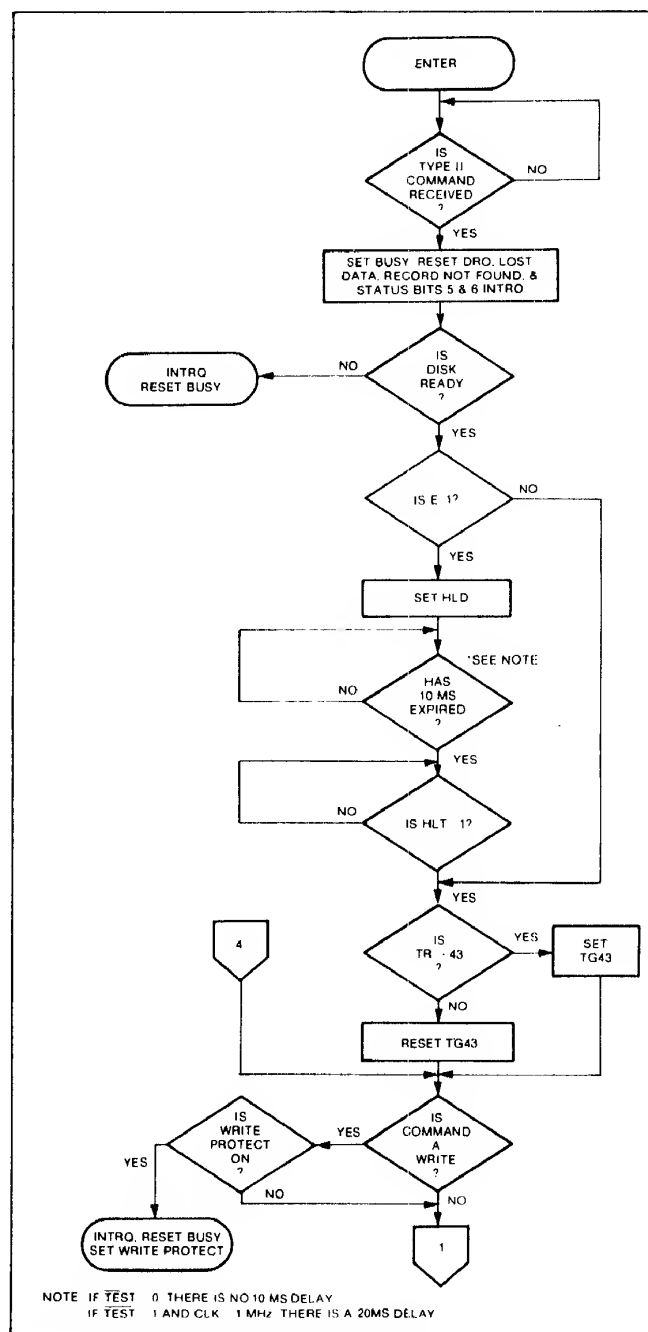

For b = 0

Sector Length Field (Hex)	Number of Bytes in Sector (Decimal)
01	16
02	32
03	48
04	64

FF	4080
00	4096

Each of the Type II commands also contain a (m) flag which determines if the multiple records (sectors) are to be read or written, depending upon the command. If m=0 a single sector is read or written and an interrupt is generated at the completion of the command. If m=1, multiple records are read or written with the sector register internally updated so that an address verification can occur on the next record. The FD1771 will continue to read or write multiple records and update the sector register until the sector register exceeds the number of sectors on the track or until the Force Interrupt command is loaded into the command register, which terminated the command and generates an interrupt.

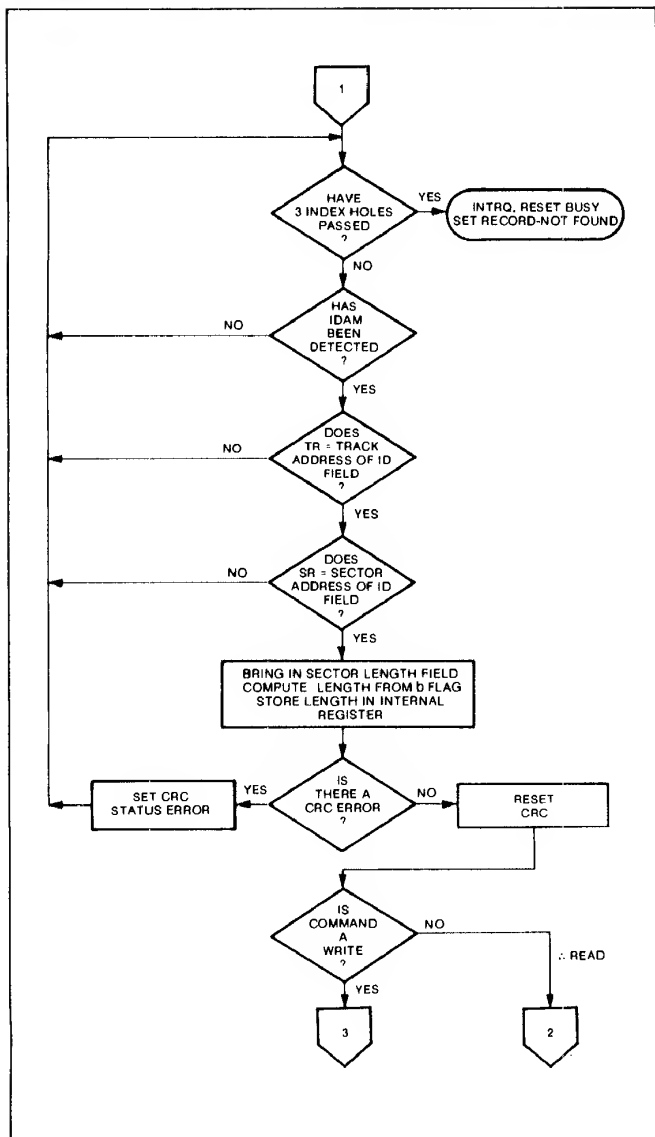

READ COMMAND

Upon receipt of the Read command, the head is loaded, the BUSY status bit set, and when an ID field is encountered that has the correct track number, correct sector number, and correct CRC, the data field is presented to the computer. The Data Address Mark of the data field must be found within 28 bytes of the correct field; if not, the Record Not Found status bit is set and the operation is terminated. When the first character or byte of the data field has been

TYPE II COMMAND FLOW

shifted through the DSR, it is transferred to the DR, and DRQ is generated. When the next byte is accumulated in the DSR, it is transferred to the DR and another DRQ is generated. If the computer has not read the previous contents of the DR before a new character is transferred that character is lost and the

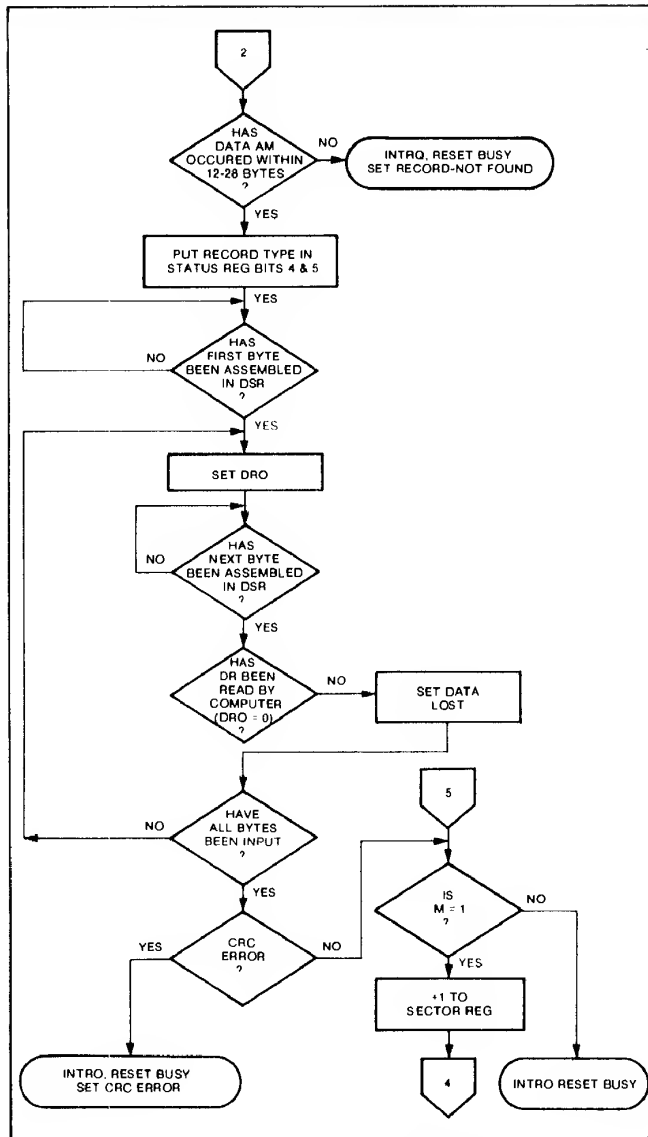

TYPE II COMMAND FLOW

Lost Data status bit is set. This sequence continues until the complete data field has been input to the computer. If there is a CRC error at the end of the data field, the CRC error status bit is set, and the command is terminated (even if it is a multiple record command).

At the end of the Read operation, the type of Data Address Mark encountered in the data field is recorded in the Status Register (Bits 5 and 6) as shown below.

Status Bit 6	Status Bit 5	Data AM (Hex)
0	0	FB
0	1	FA
1	0	F9
1	1	F8

TYPE II COMMAND FLOW

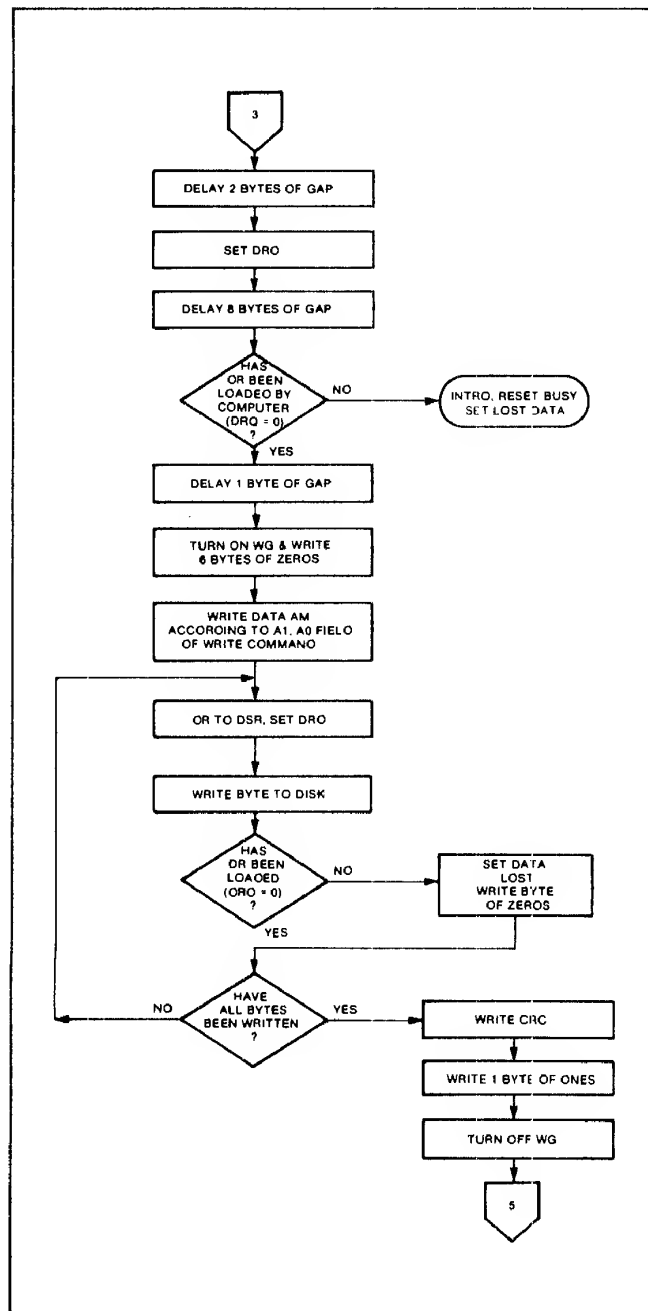

WRITE COMMAND

Upon receipt of the Write command, the head is loaded (HLD active) and the BUSY status bit is set. When an ID field is encountered that has the correct track number, correct sector number, and correct CRC, a DRQ is generated. The FD1771 counts off 11 bytes from the CRC field and the Write Gate (WG) output is made active if the DRQ is serviced (i.e., the DR has been loaded by the computer). If DRQ has not been serviced, the command is terminated and the Lost Data status bit is set. If the DRQ has been serviced, the WG is made active and six bytes of zeros are then written on the disk. At this time the Data Address Mark is then written on the disk as determined by the $a_1 a_0$ field of the command as shown on next page.

The FD1771 then writes the data field and generates DRQs to the computer. If the DRQ is not serviced in

a ₁	a ₀	Data Mark (Hex)	Clock Mark (Hex)
0	0	FB	C7
0	1	FA	C7
1	0	F9	C7
1	1	F8	C7

time for continuous writing the Lost Data status bit is set and a byte of zeros is written on the disk. The command is not terminated. After the last data byte has been written on the disk, the two-byte CRC is computed internally and written on the disk followed by one byte gap of logic ones. The WG output is then deactivated.

TYPE II COMMAND FLOW

TYPE III COMMANDS

READ Address

Upon receipt of the Read Address command, the head is loaded and the BUSY Status bit is set. The next encountered ID field is then read in from the disk, and the six data bytes of the ID field are assembled and transferred to the DR, and a DRQ is generated for each byte. The six bytes of the ID field are shown below.

TRACK ADDR	SIDE NUMBER	SECTOR ADDRESS	SECTOR LENGTH	CRC 1	CRC 2
1	2	3	4	5	6

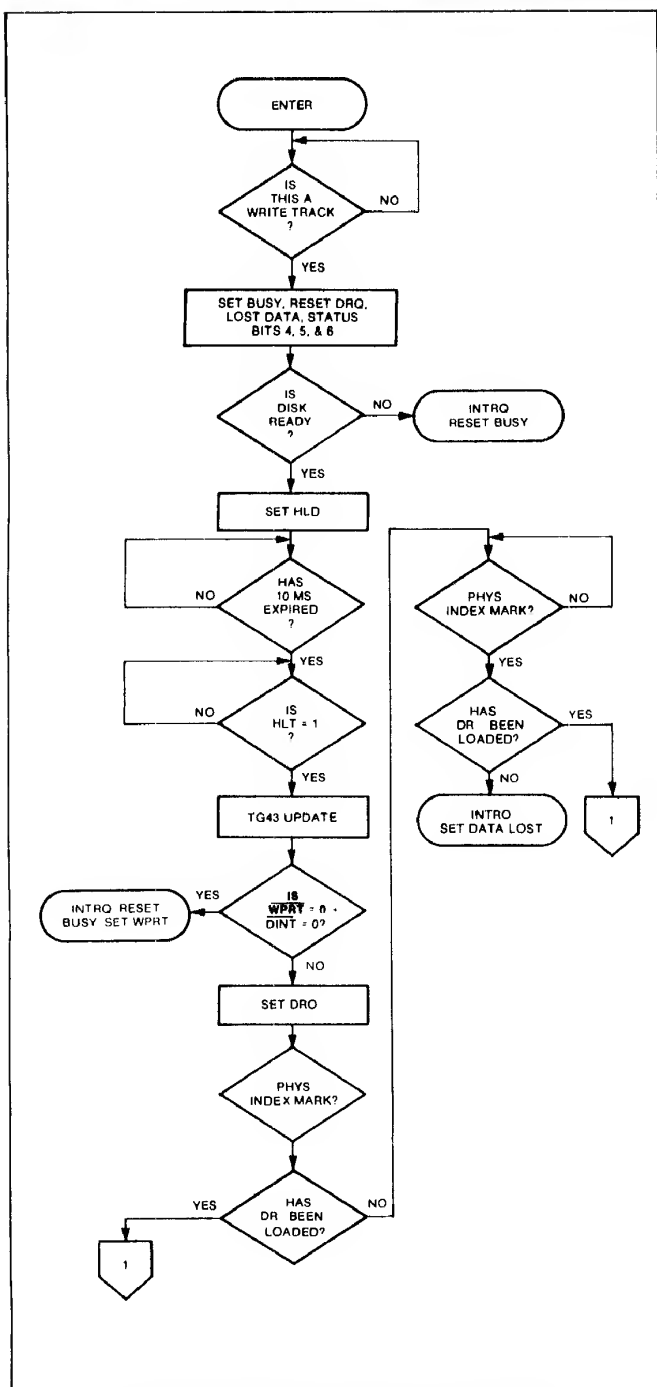

Although the CRC characters are transferred to the computer, the FD1771 checks for validity and the CRC error status bit is set if there is a CRC error. The Sector Address of the ID field is written into the Sector Register. At the end of the operation an interrupt is generated and the BUSY Status is reset.

READ TRACK

Upon receipt of the Read Track command, the head is loaded and the BUSY status bit is set. Reading starts with the leading edge of the first encountered index mark and continues until the next index pulse. As each byte is assembled it is transferred to the Data Register and the Data Request is generated for each byte. No CRC checking is performed. Gaps are included in the input data stream. If bit 0(S) of the command is a 0, the accumulation of bytes is synchronized to each Address Mark encountered. Upon completion of the command, the interrupt is activated.

WRITE TRACK

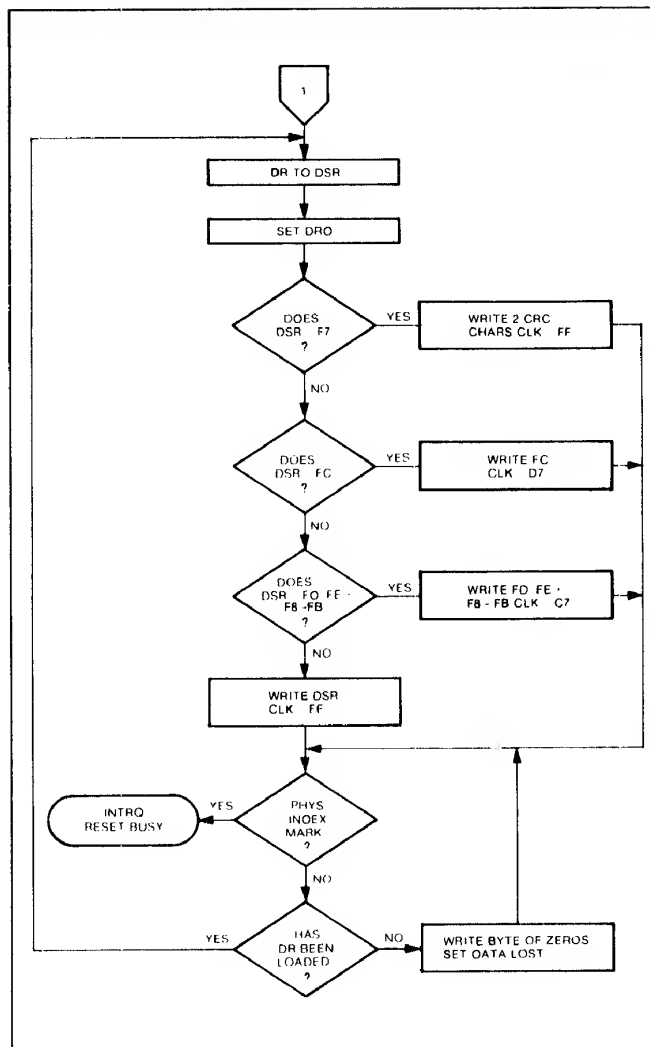

Upon receipt of the Write Track command, the head is loaded and the BUSY status bit is set. Writing starts with the leading edge of the first encountered index pulse and continues until the next index pulse, at which time the interrupt is activated. The Data Request is activated immediately upon receiving the command, but writing will not start until after the first byte has been loaded into the Data Register. If the DR has not been loaded by the time the index pulse is encountered the operation is terminated making the device Not Busy, the Lost Data status bit is set, and the Interrupt is activated. If a byte is not present in the DR when needed, a byte of zeros is substituted. Address Marks and CRC characters are written on the disk by detecting certain data byte patterns in the outgoing data stream as shown in the table below. The CRC generator is initialized when any data byte from F8 to FE is about to be transferred from the DR to the DSR.

TYPE III COMMAND WRITE TRACK

CONTROL BYTES FOR INITIALIZATION

DATA PATTERN (HEX)	INTERPRETATION	CLOCK MARK (HEX)
F7	Write CRC Character	FF
F8	Data Address Mark	C7
F9	Data Address Mark	C7
FA	Data Address Mark	C7
FB	Data Address Mark	C7
FC	Index Address Mark	D7
FD	Spare	
FE	ID Address Mark	C7

TYPE III COMMAND WRITE TRACK

The Write Track Command will not execute if the DINT input is grounded; instead, the Write Protect status bit is set and the interrupt is activated. Note that one F7 pattern generates two CRC characters.

TYPE IV COMMAND

Force Interrupt

This command can be loaded into the command register at any time. If there is a current command under execution (BUSY status bit set), the command will be terminated and an interrupt will be generated when the condition specified in the I_0 through I_3 field is detected. The interrupt conditions are shown below:

- I_0 = Not-Ready-To-Ready Transition
- I_1 = Ready-To-Not-Ready Transition
- I_2 = Every Index Pulse
- I_3 = Immediate Interrupt (Requires reset, see Note)

NOTE: If $I_0 - I_3 = 0$, there is no interrupt generated but the current command is terminated and busy is reset. This is the only command that will clear the immediate interrupt.

STATUS DESCRIPTION

Upon receipt of any command, except the Force Interrupt command, the Busy Status bit is set and the rest of the status bits are updated or cleared for the new command. If the Force Interrupt Command is received when there is a current command under execution, the Busy status bit is reset, and the rest of the status bits are unchanged. If the Force Interrupt command is received when there is not a current command under execution, the Busy Status bit is

reset and the rest of the status bits are updated or cleared. In this case, Status reflects the Type I commands.

The format of the Status Register is shown below.

(BITS)							
7	6	5	4	3	2	1	0
S7	S6	S5	S4	S3	S2	S1	S0

Status varies according to the type of command executed as shown in Table 6.

Table 6. STATUS REGISTER SUMMARY

BIT	ALL TYPE I COMMANDS	READ ADDRESS	READ	READ TRACK	WRITE	WRITE TRACK
S7	NOT READY	NOT READY	NOT READY	NOT READY	NOT READY	NOT READY
S6	WRITE PROTECT	0	RECORD TYPE	0	WRITE PROTECT	WRITE PROTECT
S5	HEAD ENGAGED	0	RECORD TYPE	0	WRITE FAULT	WRITE FAULT
S4	SEEK ERROR	ID NOT FOUND	RECORD NOT FOUND	0	RECORD NOT FOUND	0
S3	CRC ERROR	CRC ERROR	CRC ERROR	0	CRC ERROR	0
S2	TRACK 0	LOST DATA	LOST DATA	LOST DATA	LOST DATA	LOST DATA
S1	INDEX	DRQ	DRQ	DRQ	DRQ	DRQ
S0	BUSY	BUSY	BUSY	BUSY	BUSY	BUSY

STATUS FOR TYPE I COMMANDS

BIT	NAME	MEANING
S7	NOT READY	This bit when set indicates the drive is not ready. When reset it indicates that the drive is ready. This bit is an inverted copy of the READY input and logically "ored" with MR.
S6	PROTECTED	When set, indicates Write Protect is activated. This bit is an inverted copy of WRPT input.
S5	HEAD LOADED	When set, it indicates the head is loaded and engaged. This bit is a logical "and" of HLD and HLT signals.
S4	SEEK ERROR	When set, the desired track was not verified. This bit is reset to 0 when updated.
S3	CRC ERROR	When set, there was one or more CRC errors encountered on an unsuccessful track verification operation. This bit is reset to 0 when updated.
S2	TRACK 00	When set, indicates Read-Write head is positioned to Track 0. This bit is an inverted copy of the TR00 input.
S1	INDEX	When set, indicates index mark detected from drive. This bit is an inverted copy of the IP input.
S0	BUSY	When set, command is in progress. When reset, no command is in progress.

STATUS BITS FOR TYPE II AND III COMMANDS

BIT	NAME	MEANING
S7	NOT READY	This bit when set indicates the drive is not ready. When reset, it indicates that the drive is ready. This bit is an inverted copy of the READY input and "ored" with MR. The TYPE II and III Commands will not execute unless the drive is ready.
S6	RECORD TYPE/ WRITE PROTECT	On Read Record: It indicates the MSB of record-type code from data field address mark. On Read Track: Not Used. On any Write Track: It indicates a Write Protect. This bit is reset when updated.
S5	RECORD TYPE/WRITE FAULT	On Read Record: It indicates the LSB of record-type code from data field address mark. On Read Track: Not Used. On any Write Track: It indicates a Write Fault. This bit is reset when updated.
S4	RECORD NOT FOUND	When set, it indicates that the desired track and sector were not found. This bit is reset when updated.
S3	CRC ERROR	If S4 is set, an error is found in one or more ID fields; otherwise it indicates error in data field. This bit is reset when updated.
S2	LOST DATA	When set, it indicates the computer did not respond to DRQ in one byte time. This bit is reset to zero when updated.
S1	DATA REQUEST	This bit is a copy of the DRQ output. When set, it indicates the DR is full on a Ready operation or the DR is empty on a Write operation. This bit is reset to zero when updated.
S0	BUSY	When set, command is under execution. When reset, no command is under execution.

FD1771-01

FORMATTING THE DISK (Refer to section on Type III Commands for flow diagrams.)

Formatting the disk is a relatively simple task when operating programmed I/O or when operating under DMA control with a large amount of memory. When operating under DMA with limited amount of memory, formatting is a more difficult task. This is because gaps as well as data must be provided at the computer interface.

Formatting the disk is accomplished by positioning the R/W head over the desired track number and issuing the Write Track command. Upon receipt of the Write Track command, the FD1771 raises the Data Request signal. At this point in time, the user loads the Data Register with desired data to be written on the disk. For every byte of information to be written on the disk, a Data Request is generated. This sequence continues from one index mark to the next index mark. Normally, whatever data pattern appears in the Data Register is written on the disk with a clock mark of (FF)₁₆. However, if the FD1771 detects a data pattern on F7 through FE in the Data Register, this is interpreted as data address marks with missing clocks or CRC generation. For

instance, an FE pattern will be interpreted as an ID address mark (DATA-FE, CLK-C7) and the CRC will be initialized. An F7 pattern will generate two CRC characters. As a consequence, the patterns F7 through FE must not appear in the gaps, data fields, or ID fields. Also, CRCs must be generated by an F7 pattern.

Disks may be formatted in IBM 3740 formats with sector lengths of 128,256,512, or 1024 bytes, or may be formatted in non-IBM format with sector lengths of 16 to 4096 bytes in 16-byte increments. IBM 3740 at the present time only defines two formats. One format with 128 bytes/sector and the other with 256 bytes/sector. The next section deals with the IBM 3740 format with 128 bytes/sector followed by a section of non-IBM formats.

IBM 3740 Formats — 128 Bytes/Sector

The IBM format with 128 bytes/sector is depicted in the Track Format figure on the following page. In order to create this format, the user must issue the Write Track command, and load the data register with the following values. For every byte to be written, there is one data request.

Number of Bytes	Hex Value of Byte Written
40	00 or FF
6	00
1	FC (Index Mark)
* 26	00 or FF
6	00
1	FE (ID Address Mark)
1	Track Number (0 through 4C)
1	00
1	Sector Number (1 through 1A)
1	00
1	F7 (two CRCs written)
11	00 or FF
6	00
1	FB (Data Address Mark)
128	Data (IBM uses E5)
1	F7 (two CRCs written)
27	00 or FF
247 **	00 or FF

*Write bracketed field 26 times.

**Continue writing until FD1771 interrupts out. Approximately 247 bytes.

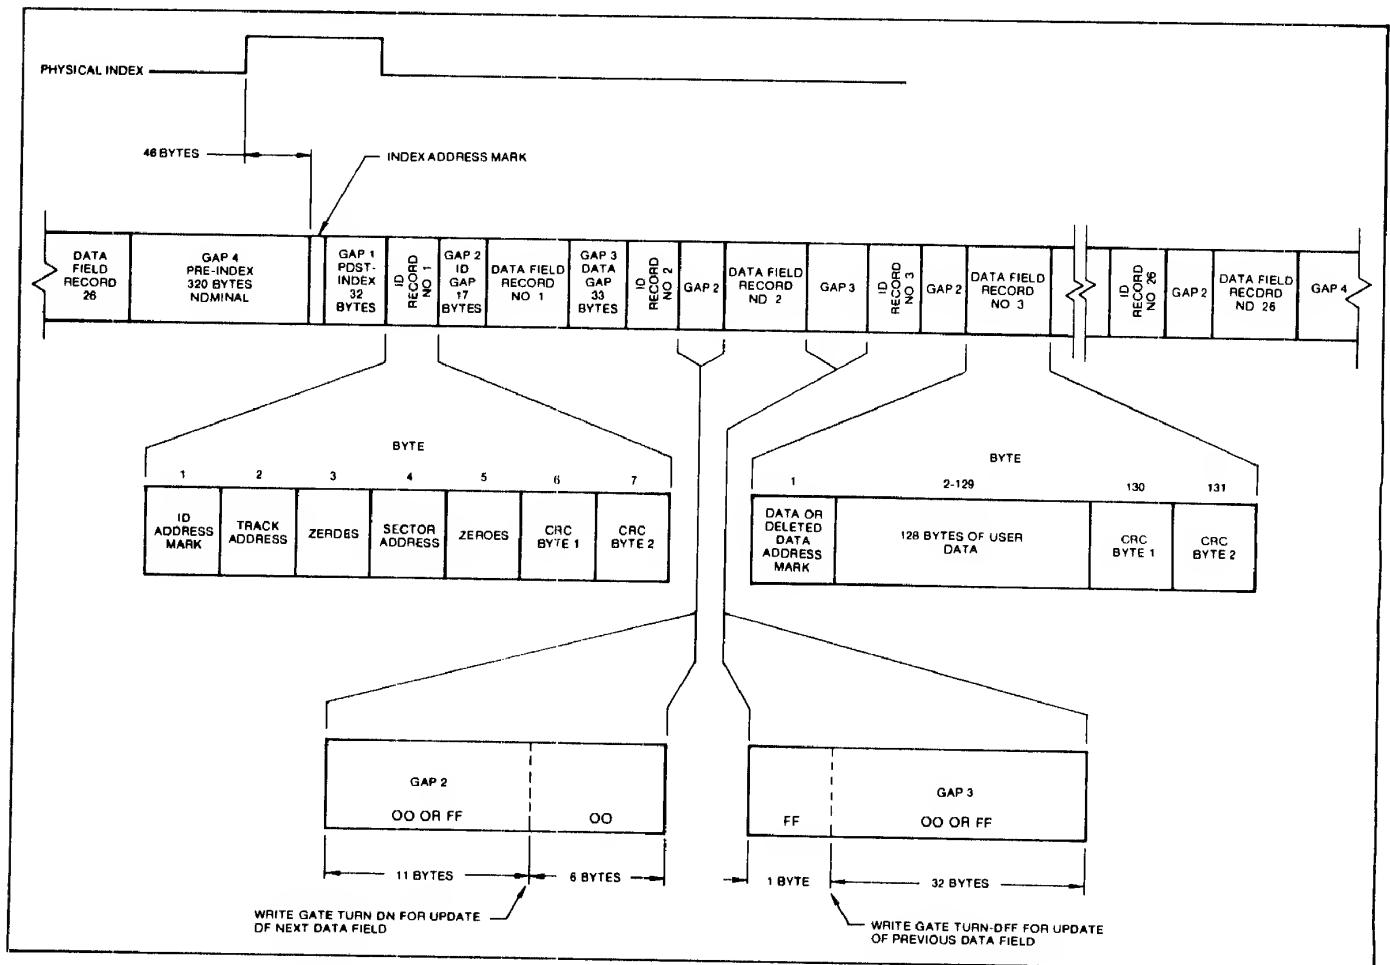

Non-IBM Formats

Non-IBM formats are very similar to the IBM formats except a different algorithm is used to ascertain the sector length from the sector length byte in the ID field. This permits a wide range of sector lengths from 16 to 4096 bytes. Refer to Section V, Type II commands with b flag equal to zero. Note that F7 through FE must not appear in the sector length byte of the ID field.

In formatting the FD1771, only two requirements regarding GAP sizes must be met. GAP 2 (i.e., the gap between the ID field and data field) must be 17 bytes of which the last 6 bytes must be zero and that every address mark be preceded by at least one byte of zeros. However, it is recommended that every GAP be at least 17 bytes long with 6 bytes of zeros. The FD1771 does not require the index address mark (i.e., DATA = FC, CLK = D7) and need not be present.

1771-01 Application Notes

INTRODUCTION

The FD1771-01 Floppy Disk Formatter/Controller is a MOS/LSI device designed to ease the task of interfacing the 8" or 5¼ (mini-floppy) disk drive to a host processor. It is ideally suited for a wide range of microprocessors, providing an 8-bit bi-directional interface to the CPU for all control and data transfers. Requiring standard +12, ±5V power supplies, the 1771 is available in ceramic or plastic 40 pin dual-in-line packages.

The 1771 has been designed to be compatible with the IBM 3740 standard. This single-density Frequency Modulated (FM) recording technique, records a clock bit between a data bit serially on each track. Figure 1 illustrates how a HEX "D2" is recorded. Note that when the data bit to be written is zero, no pulse or flux transition is recorded. For the 8" drive, there are 77 tracks, with 26 sectors on each track. Each sector contains 128 bytes of data. Although there is no "standard" format for the mini-floppy, most manufacturers utilize either 35 or 40 tracks per side, with 16 sectors of 128 bytes each per track. Both the 8" and 5¼" formats must be soft-sectored, i.e., there are no physical holes to denote sector locations. The hard-sectored disk has been losing popularity, mainly due to the fact that the sector lengths cannot be increased.

Being soft-sector compatible, the 1771 must know where each sector begins on the track. This is performed by using Address Marks. These bytes are recorded on the disk with certain clock pulses missing, and are unique from all other data and gap bytes recorded on the track. Six distinct Address Marks can be used:

Description	Data	Clock Pattern
Index Address Mark	FC	D7
ID Address Mark	FE	C7
Data Address Mark	FB	C7
User defined	FA	C7
User Defined	F9	C7
Deleted Address Mark	F8	C7

The two "User Defined" Address Marks are unique to the 1771, and do not appear in the IBM 3740 standard. These Address Marks can be used to

define the type of data i.e., "object" or "text" data, alternate sector data, or any other purpose the user chooses.

PROCESSOR INTERFACE

The 1771 contains five internal registers that can be accessed via the 8-bit DAL lines by the CPU. These registers are used to control the movement of the head, read and write sectors, and perform all other functions at the drive. Regardless of the operation performed, it must be initiated through one or more of these registers. They are selected by a proper binary code on the A0, A1 lines in conjunction with the \overline{RE} and \overline{WE} lines when the device is selected. The registers and their addresses are:

\overline{CS}	A ₁	A ₀	$\overline{RE} = 0$	$\overline{WE} = 0$
0	0	0	STATUS REG	COMMAND REG
0	0	1	TRACK REG	TRACK REG
0	1	0	SECTOR REG	SECTOR REG
0	1	1	DATA REG	DATA REG
1	X	X	Deselected	Deselected

Command Register: This is a write-only register used to send all commands to the 1771.

Status Register: This is a read-only register that must be read at the completion of every command to determine whether execution was successful. It may also be used to monitor command execution, and to sense when data is required by the drive for read or write operations.

Track Register: This R/W register holds the current position of the R/W head.

Sector Register: This R/W register holds the desired sector number for read and write commands.

Data Register: This R/W register contains the data to be read or written to a particular sector.

INTERRUPTS

There are two INTERRUPT lines for CPU use. These are the DRQ (Data Request) and INTRQ (Interrupt Request). These are active high, open drain outputs and require a pull-up resistor of 10K or greater to +5V. Both of these signals also appear in the status register as the Busy (INTRQ) and the data request (DRQ) bits. The user has the option of utilizing these hardware lines for system interrupts, or through

software by polling the status register. The choice is dependent upon the particular microprocessor and support hardware of the system.

INTRQ: This line is used to signify the completion of any command. It is reset low when a new command is loaded into the command register, or when the status register is read.

DRQ: This line is active high whenever the data register requires servicing. During a read command, it signifies that the data register contains a byte of data from the disk and may be read by the CPU. During a write command, it signifies that the data register is empty and may be loaded with the next byte to be written on the disk. The DRQ line is reset whenever the data register is read or written to. It is also reset when a new command is loaded into the command register, providing the new command is not a Forced Interrupt, and the 1771 is not busy (Busy Bit = 0).

WRITE SECTOR

With the use of the WRITE SECTOR command, the CPU can access any desired sector(s) in a track. Prior to loading this command, the R/W head of the drive must be positioned over the specific track. This can be first accomplished with the use of any of the Type I commands. Once positioned, the CPU must load the desired sector number into the sector register, then issue the command. The head will load, and the 1771 will begin searching for the correct ID field. If the correct sector and track is not found within 2 revolutions of the disk, the RECORD-NOT-FOUND bit will be set in the status register, and the command will be terminated. Once found, the 1771 will issue a DRQ in request of the first data byte to be written. Once the data register is loaded, the 1771 will issue a DRQ for each byte to be recorded, until the entire sector is written. For the 8" drive, the user must load the data register 24 microseconds after a DRQ is generated. Failure to meet this time will cause the lost data bit to be set, and a byte of zeros substituted and written on the disk.

READ SECTOR

The READ SECTOR command functions in much the same way as the WRITE SECTOR command. The sector register must again be loaded with the desired sector number, before the read command can be loaded. After the ID field has been found, the 1771 will begin generating DRQ's, with the data register being loaded with each byte of the sector field. For the 8" drive, the user must read the data register at least 26 microseconds after the DRQ is generated. Failure to meet this time will cause the lost data bit to be set in the status register, while the next assembled byte will overwrite the contents of the data register.

Both the Read and Write sector commands also

contain an "m" flag for accessing multiple sectors. The sector register is incremented internally after each sector is read or written to. Eventually the sector register will exceed the physical number of sectors on the track. The user can either issue the Forced Interrupt command after the last sector, or wait for the 1771 to interrupt out. In the latter case, the RECORD-NOT-FOUND status bit will be set.

FLOPPY DISK INTERFACE

For the most part, the actual Floppy Disk Interface will consist mainly of Buffer/Drivers. Most drives manufactured today require an open collector TTL interface, with appropriate resistor terminal networks. Figure 2 shows the interface of the 1771 to a Shugart SA400 Drive. Aside from the data separator, the interface consists mainly of 7438's and 7414 TTL gates. A 9602 one-shot is used for the desired head load delay. In this illustration, the 6800 microprocessor is used via a 6820 Peripheral Interface Adapter to control all functions of the 1771. Similarly, other parallel port devices (such as the 8255 for 8080 systems) can be used for the interface, or the 1771 may simply be tied directly to the systems data bus and control lines, providing TTL loading factors are observed.

DATA SEPERATION

The internal DATA SEPERATOR of the 1771 can be used by tying the XTDS line high, and supplying the combined clock and data pulses on the FD data line. In order to maintain an error rate better than 1 in 10^8 , and external data separator is recommended.

Since the 1771 system clock is at 2 MHz, this allows for a 500 ns resolution. The internal data window will move 500 ns with respect to the incoming data bit. On the inner tracks of the drive, the bit shift is more severe and may occasionally cause a data or clock bit to fall outside of this data window. Since the 1771 will perform up to 5 retries, this error rate may be acceptable for some applications.

When the XTDS line is forced low, the 1771 will accept separated clock and data on the FDCLOCK and FDDATA lines. Figure 3 illustrates the timing of these signals. The actual FDCLOCK and FDDATA lines may be reversed; the 1771 will determine which line is clock and which is data when an Address Mark is detected. This feature greatly simplifies the design of the data separator.

Figure 4 illustrates the Phase-Lock Loop method for data separation. The circuit operates at 8 MHz, or 32 times the frequency of a received bit cell. The MC4024 VCO is used to supply the nominal clock frequency. The first 74LS161 counter provides a divide by 16 frequency and a carry to one side of the MC4044 phase detector. The other input of the MC4044 is tied to another 74LS161 counter which is affected by the incoming data stream. The output of

the phase detector is a signal proportional to the differences of the incoming pulses. This is then fed through a low pass filter, and to the input of the MC4024 to adjust the output frequency. Figures 5 thru 8 illustrate other types of data separators.

These employ the "Counter Separator" techniques and are quite different from the Phase-Lock-Loop method. With the addition of "One-Shot" delay element or an input clock, most of the complexity of the PPL circuit can be eliminated.

FD1781/FD1781-01 Floppy Disk Formatter/Controller

FD1781/FD1781-01

FEATURES

- SOFT SECTOR FORMAT COMPATIBILITY
- AUTOMATIC TRACK SEEK WITH VERIFICATION
- ACCOMMODATES SINGLE AND DOUBLE DENSITY FORMATS
- READ MODE
Single/Multiple Record Read with Automatic Sector Search or Entire Track Read
Selectable 128 Byte or Variable Length Record
- WRITE MODE
Single/Multiple Record Write with Automatic Sector Search
Entire Track Write for Diskette Initialization
- PROGRAMMABLE CONTROLS
Selectable Track to Track Stepping Time
Selectable Head Settling and Head Engage Times
- SYSTEM COMPATIBILITY
Double Buffering of Data 8 Bit Bi-Directional Bus for Data, Control and Status
DMA or Programmed Data Transfers
All Inputs and Outputs are TTL Compatible
On-chip Track and Sector Registers Comprehensive Status Information

APPLICATIONS

FLOPPY DISK DRIVE INTERFACE
SINGLE OR MULTIPLE DRIVE CONTROLLER/
FORMATTER
NEW MINI-FLOPPY CONTROLLER

GENERAL DESCRIPTION

The FD1781 is a MOS/LSI device that performs the functions of a Floppy Disk Controller/Formatter. The device is designed to be included in the disk drive electronics, and contains a flexible interface organization that accommodates the interface signals from most drive manufacturers. When in the single density mode the FD1781 is fully IBM-3740 compatible. In the double density mode, the type of encoding scheme is a function of the user's data recovery circuits. In this manner both M²FM or MFM is obtainable.

In Double Density Mode, the FD1781 allows 17 bytes for CAP2, while the FD1781-01 allows 34 bytes for this field. All other gap lengths can be fully defined by the user.

The FD1781 is fabricated in N-channel Silicon Gate MOS technology and is TTL compatible on all inputs and outputs.

Figure 1. 1781 SYSTEM BLOCK DIAGRAM

PIN OUTS

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION																				
20 21 40 19	POWER SUPPLIES MASTER RESET	VSS VCC VDD MR	Ground + 5V + 12V A logic low on this input resets the device and clears the command register. The Not Ready (Status Bit 7) is reset during MR ACTIVE. When MR is brought to a logic high a Restore Command is executed, regardless of the state of the Ready signal from the drive.																				
COMPUTER INTERFACE:																							
7-14	DATA ACCESS LINES	DAL0-DAL7	Eight bit inverted Bidirectional bus used for transfer of data, control, and status. This bus is a receiver enabled by WE or a transmitter enabled by RE.																				
3	CHIP SELECT	CS	A logic low on this input selects the chip and enables computer communication with the device.																				
5,6	REGISTER SELECT LINES	A0,A1	These inputs select the register to receive/transfer data on the DAL lines under RE and WE control: <table> <tr> <th>A1</th><th>A0</th><th>RE</th><th>WE</th></tr> <tr> <td>0</td><td>0</td><td>Status Reg</td><td>Command Reg</td></tr> <tr> <td>0</td><td>1</td><td>Track Reg</td><td>Track Reg</td></tr> <tr> <td>1</td><td>0</td><td>Sector Reg</td><td>Sector Reg</td></tr> <tr> <td>1</td><td>1</td><td>Data Reg</td><td>Data Reg</td></tr> </table>	A1	A0	RE	WE	0	0	Status Reg	Command Reg	0	1	Track Reg	Track Reg	1	0	Sector Reg	Sector Reg	1	1	Data Reg	Data Reg
A1	A0	RE	WE																				
0	0	Status Reg	Command Reg																				
0	1	Track Reg	Track Reg																				
1	0	Sector Reg	Sector Reg																				
1	1	Data Reg	Data Reg																				
4	READ ENABLE	RE	A logic low on this input controls the placement of data from a selected register on the DAL when CS is low.																				
2	WRITE ENABLE	WE	A logic low on this input gates data on the DAL into the selected register when CS is low.																				
38	DATA REQUEST	DRQ	This open drain output indicates that the DR contains assembled data in Read operations, or the DR is empty in Write operations. This signal is reset when serviced by the computer through reading or loading the DR in Read or Write operation, respectively. Use 10K pull-up resistor to +5.																				
39	INTERRUPT REQUEST	INTRQ	This open drain output is set at the completion or termination of any operation and is reset when a new command is loaded into the command register. Use 10K pull-up resistor to +5.																				
24	CLOCK	CLK	This input requires a free-running square wave clock for internal timing reference.																				
FLOPPY DISK INTERFACE:																							
25	ADDRESS MARK DETECT IN	AMIN	Indicates to the FD1781 that an address mark has been detected. The FD1781 assumes the next three data bits defines the type of address mark encountered.																				
26 27	INPUT STROBE INPUT DATA	INSTR INDATA	Indicates that INDATA is VALID. The external data recovery circuits present INDATA as an input to the FD1781. INDATA must be valid when INSTR is active, see timing.																				
31	OUTPUT DATA	OTDATA	The FD1781 presents output data and is valid when OTSTR is active.																				
28	HEAD LOAD	HLD	The HLD output controls the loading of the Read-Write head against the media. The HLT																				

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
23	HEAD LOAD TIMING	HLT	input is sampled every 15 nsec. When a logic high is found on the HLT input the head is assumed to be engaged.
15	STEP	STEP	Step and direction motor control. The step output contains a 2 μ sec high signal for each step and the direction output is active high when stepping in, active low when stepping out.
16	DIRECTION	DIRC	OTSTR when active indicates when the Output data is valid. The leading edge of OTSTR is centered about the data. (See timing) OTSTR becomes Write Data (WD) when $\overline{\text{DDEN}} = 1$.
17	OUTPUT STROBE	OTSTR	
18	ADDRESS MARK OUT	AMOT	AMOT when active informs the external data recovery circuits to write a unique data mark in double density mode. AMOT is valid for three data bits if CLK mark = C7.
29	TRACK GREATER THAN 43	TG43	This output informs the drive that the Read-Write head is positioned between track 44-76. This output is valid only during Read and Write Commands.
30	WRITE GATE	WG	This output is made valid when writing is to be performed on the diskette.
32	READY	READY	This input indicates disk readiness and is sampled for a logic high before Read or Write commands are performed. If Ready is low the Read or Write operation is not performed and an interrupt is generated. A Seek operation is performed regardless of the state of Ready. The Ready input appears in inverted format as Status Register bit 7.
33	WRITE FAULT	$\overline{\text{WF}}$	This input detects writing faults indications from the drive. When $\text{WG} = 1$ and $\overline{\text{WF}}$ goes low the current Write command is terminated and the Write Fault status bit is set. The $\overline{\text{WF}}$ input should be made inactive (high) when WG becomes inactive.
34	$\overline{\text{TRACK 00}}$	$\overline{\text{TR00}}$	This input informs the FD1781 that the Read-Write head is positioned over Track 00 when a logic low.
35	$\overline{\text{INDEX PULSE}}$	$\overline{\text{IP}}$	Input, when low for a minimum of 10 μ sec, informs the FD1781 when an index mark is encountered on the diskette.
36	$\overline{\text{WRITE PROTECT}}$	$\overline{\text{WPRT}}$	This input is sampled whenever a Write Command is received. A logic low terminated the command and sets the Write Protect Status bit.
37	$\overline{\text{DOUBLE DENSITY}}$	$\overline{\text{DDEN}}$	This pin selects either single or double density operation. When $\overline{\text{DDEN}} = 0$, double density is selected. When $\overline{\text{DDEN}} = 1$, single density is selected.
22	TEST	TEST	This input is used for testing purposes only and should be tied to +5V or left open by the user.

ORGANIZATION

The Floppy Disk Formatter block diagram is illustrated above. The primary sections include the parallel processor interface and the Floppy Disk interface.

Data Shift Register — This 8-bit register assembles serial data from the Read Data input (INDATA) during Read operations and transfers serial data to the Write Data output during Write operations.

Data Register — This 8-bit register is used as a holding register during Disk Read and Write operations. In Disk Read operations the assembled data byte is transferred in parallel to the Data Register from the Data Shift Register. In Disk Write operations information is transferred in parallel from the Data Register to the Data Shift Register.

When executing the Seek command the Data Register holds the address of the desired Track position. This register can be loaded from the DAL and gated onto the DAL under processor control.

Track Register — This 8-bit register holds the track number of the current Read/Write head position. It is incremented by one every time the head is stepped in (towards track 76) and decremented by one when the head is stepped out (towards track 00). The contents of the register are compared with the recorded track number in the ID field during disk Read, Write, and Verify operations. The Track Register can be loaded from or transferred to the DAL. This Register should not be loaded when this device is busy.

Sector Register (SR) — This 8-bit register holds the address of the desired sector position. The contents of the register are compared with the recorded sector number in the ID field during disk Read or Write operations. The Sector Register contents can be loaded from or transferred to the DAL. This register should not be loaded when the device is busy.

Command Register (CR) — This 8-bit register holds the command presently being executed. This register should not be loaded when the device is busy unless the execution of the current command is to be overridden. This latter action results in an interrupt. The command register can be loaded from the DAL, but not read onto the DAL.

Status Register (STR) — This 8-bit register holds device Status information. The meaning of the Status bits are a function of the contents of the Command Register. This register can be read onto the DAL, but not loaded from the DAL.

CRC Logic — This logic is used to check or to generate the 16-bit Cyclic Redundancy Check (CRC). The polynomial is: $G(x) = x^{16} + x^{12} + x^5 + 1$.

The CRC includes all information starting with the address mark and up to the CRC characters. The CRC register is preset to ones prior to data being shifted through the circuit.

Arithmetic/Logic Unit (ALU) — The ALU is a serial comparator, incrementer, and decrementer and is used for register modification and comparisons with the disk recorded ID field.

Timing and Control — All computer and Floppy Disk Interface controls are generated through this logic. The internal device timing is generated from an external crystal clock.

The FD1781 has two different modes of operation according to the state of \overline{DDEN} . When $\overline{DDEN} = 0$ double density is assumed. When $\overline{DDEN} = 1$, single density is assumed. During disk read operations, the user must provide both data recovery and address mark detection circuits external to FD1781 in both single and double density modes. Thus for disk read operations, the user must provide as an input to the FD1781 Data (INDATA) a strobe to indicate when the data is valid (INSTR) and address mark detect (AMIN). During disk write operations and in the double density mode, the FD1781 provides as outputs Data (OTDATA), a strobe to indicate validity (OTSTR) and Address Mark Out (AMOT). During disk write operation and in the single density mode, OTSTR becomes Write Data (WD) which is exactly the same as in the FD1771.

PROCESSOR INTERFACE

The interface to the processor is accomplished through the eight Data Access Lines (DAL) and associated control signals. The DAL are used to transfer Data, Status, and Control words out of, or into the FD1781. The DAL are three state buffers that are enabled as output drivers when Chip Select (\overline{CS}) and Read Enable (\overline{RE}) are active (low logic state) or act as input receivers when \overline{CS} and Write Enable (\overline{WE}) are active.

When transfer of data with the Floppy Disk Controller is required by the host processor, the device address is decoded and \overline{CS} is made low. The least-significant address bits A1 and A0, combined with the signals \overline{RE} during a Read operation or \overline{WE} during a Write operation are interpreted as selecting the following registers:

A1-A0	READ (\overline{RE})	WRITE (\overline{WE})
0 0	Status Register	Command Register
0 1	Track Register	Track Register
1 0	Sector Register	Sector Register
1 1	Data Register	Data Register

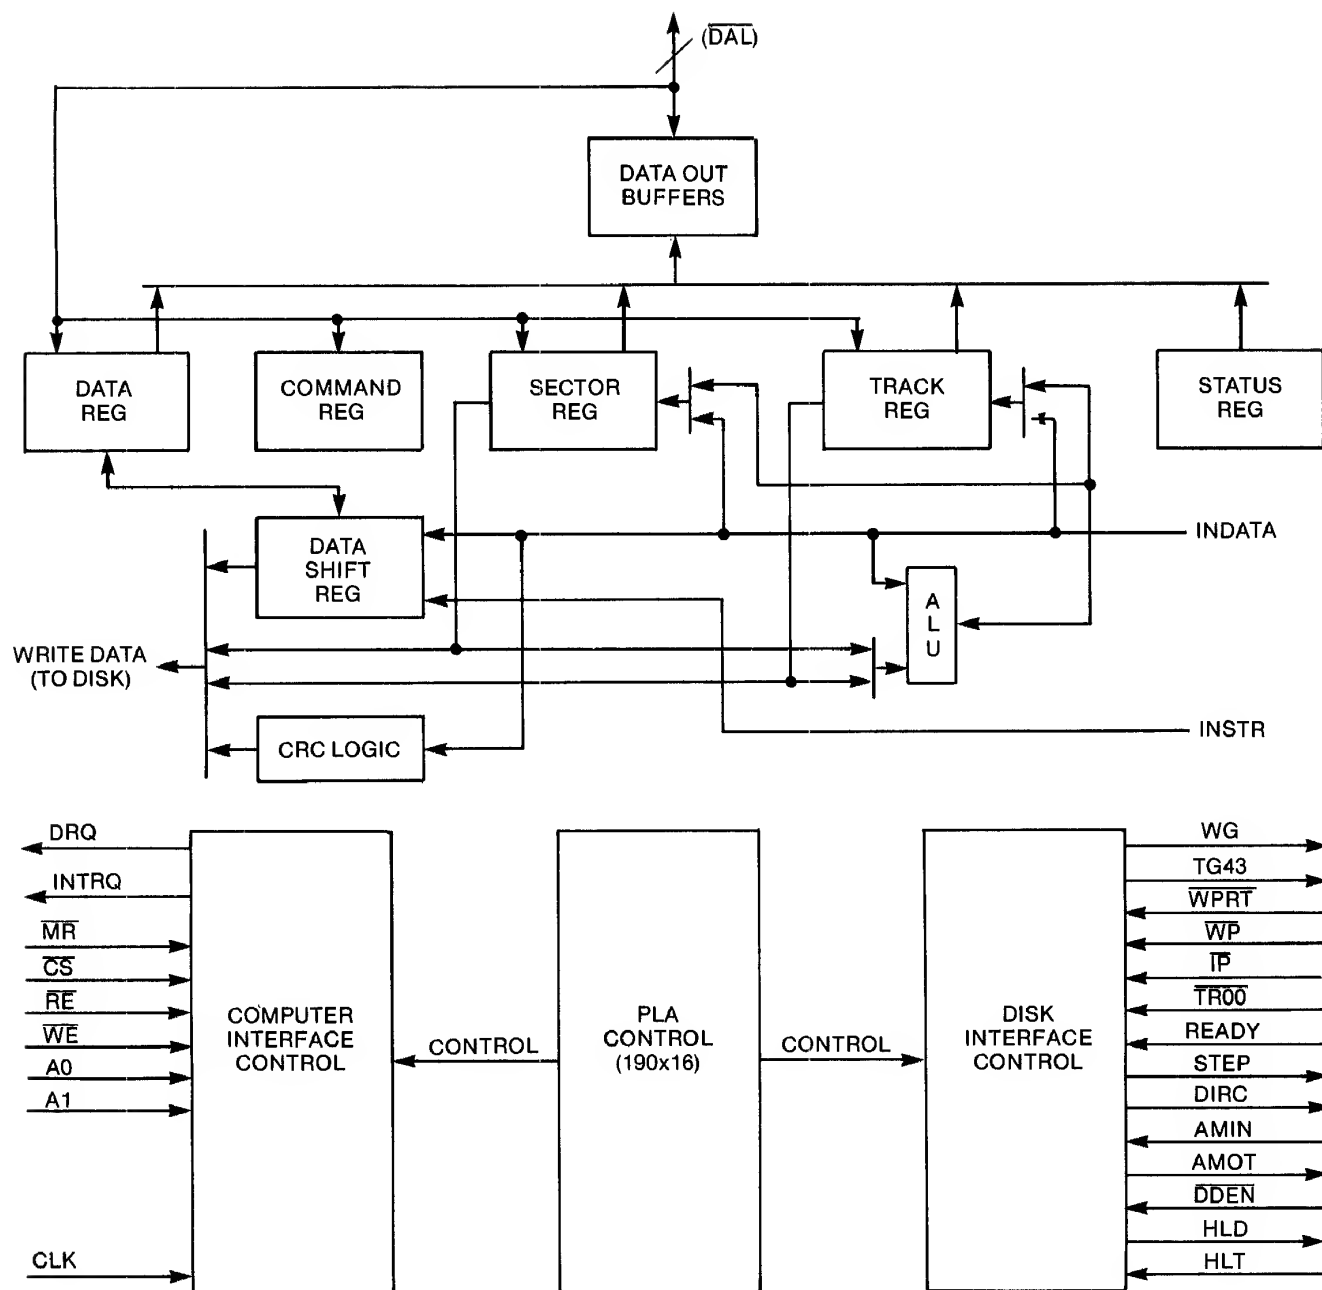

Figure 3. FD1781 BLOCK DIAGRAM

During Direct Memory Access (DMA) types of data transfers between the Data Register of the FD1781 and the processor, the Data Request (DRQ) output is used in Data Transfer control. This signal also appears as status bit 1 during Read and Write operations.

On Disk Read operations the Data Request is activated (set high) when an assembled serial input byte is transferred in parallel to the Data Register. This bit is cleared when the Data Register is read by the processor. If the Data Register is read after one or more characters are lost, by having new data transferred into the register prior to processor readout, the Lost Data bit is set in the Status Register. The Read operation continues until the end of sector is reached.

On Disk Write operations the Data Request is activated when the Data Register transfers its contents to the Data Shift Register, and requires a new data byte. It is reset when the Data Register is loaded with new data by the processor. If new data is not loaded at the time the next serial byte is required by the Floppy Disk, a byte of zeroes is written on the diskette and the Lost Data bit is set in the Status Register.

The Lost Data bit and certain other bits in the Status Register will activate the interrupt request (INTRQ). The interrupt line is also activated with normal completion or abnormal termination of all controller operations. The INTRQ signal remains active until reset by reading the Status Register to the processor or by the loading of the Command Register. In addition, the INTRQ is generated if a Force Interrupt command condition is met.

FLOPPY DISK INTERFACE

The Floppy Disk interface consists of head positioning controls, write gate controls, and data transfers. The Clock (CLK) input is normally a free-running 2 MHz $\pm 1\%$ when in the double density mode and 1 MHz $\pm 1\%$ when in the single density mode. However when using a mini-floppy, the CLK is normally 1 MHz when in double density mode and 1/2 MHz when in the single density mode.

HEAD POSITIONING

Four commands cause positioning of the Read-Write head (see Command Section). The period of each positioning step is specified by the r field in bits 1 and 0 of the command word. After the last directional step an additional 15 milliseconds of head settling time takes place. The four programmable stepping rates are tabulated below.

The rates (shown in Table 1) can be applied to a Step-Direction Motor through the device interface.

Step — A 2 μ s pulse is provided as an output to the drive. For every step pulse issued, the drive moves one track location in a direction determined by the direction output.

Direction (DIRC) — The Direction signal is active high when stepping in and low when stepping out. The Direction signal is valid 12 μ s before the first stepping pulse is generated.

When a Seek, Step or Restore command is executed an optional verification of Read-Write head position can be performed by setting bit 2 in the command word to a logic 1. The verification operation begins at the end of the 15 millisecond settling time after the head is loaded against the media. The track number from the first encountered ID Field is compared against the contents of the Track Register. If the track numbers compare and the ID Field Cyclic Redundancy Check (CRC) is correct, the verify operation is complete. If track comparison is not made but the CRC checks, an interrupt is generated, the Seek Error status (Bit 4) is set and the Busy status bit is preset.

TABLE 1
STEPPING RATES

CLK	2 MHz	1 MHz	1 MHz	1/2 MHz	2 MHz	1 MHz
DDEN	0	1	0	1		
R1 R0	TEST = 1	TEST = 1	TEST = 1	TEST = 1	TEST = 0	TEST = 0
0 0	3 ms	3 ms	6 ms	6 ms	Approx. 400 μ s	Approx. 800 μ s
0 1	6 ms	6 ms	12 ms	12 ms		
1 0	10 ms	10 ms	20 ms	20 ms		
1 1	20 ms	20 ms	40 ms	40 ms		

The Head Load (HDL) output controls the movement of the read/write head against the disk for data recording or retrieval. It is activated at the beginning of a Read, Write (E Flag On) or Verify Operation, or a Seek or Step operation with the head load bit, h, a logic one, and remains activated until the 15th index pulse following the last operation which uses the read/write head. Reading or Writing does not occur until a minimum of 15 msec delay after the HDL signal is made active. If executing the type 2 commands with the E flag off, there is no 15 msec delay and the head is assumed to be engaged. The delay is determined by sampling of the Head Load Timing (HLT) input every 15 msec. A high logic state input, generated from the Head Load output transition and delayed externally, identifies engagement of the head against the disk. In the Seek and Step commands, the head is loaded at the start of the command execution when the h bit is a logic one. In a verify command the head is loaded after stepping to the destination track on the disk whenever the h bit is a logic zero.

DISK READ OPERATION

The normal sector length for Read or Write operations with the IBM 3740 format is 128 bytes. This

format or binary multiples of 128 bytes will be adopted by setting a logic 1 in Bit 3 of the Read Track and Write Track commands. Additionally, a variable sector length feature is provided which allows an indicator recorded in the ID Field to control the length of the sector. Variable sector lengths can be read or written in Read or Write commands respectively by setting a logic 0 in Bit 3 of the command word. The sector length indicator specifies the number of 16 byte groups or $16 \times N$, where N is equal to 1 to 256 groups. An indicator of all zeroes is interpreted as 256 sixteen byte groups.

DISK WRITE OPERATION

When writing is to take place on the diskette the Write Gate (WG) output is activated, allowing current to flow into the Read/Write head. As a precaution to erroneous writing the first data byte must be loaded into the Data Register in response to a Data Request from the FD1781 before the Write Gate signal can be activated.

Writing is inhibited when the Write Protect input is a logic low, in which case any Write command is immediately terminated, an interrupt is generated and the Write Protect status bit is set. The Write Fault input, when activated, signifies a writing fault condition detected in disk drive electronics such as failure to detect write current flow when the Write Gate is activated. On detection of this fault the FD1781 terminates the current command, and sets the Write Fault bit (bit 5) in the Status Word. The Write Fault input should be made inactive when the Write Gate output becomes inactive.

Whenever a Read or Write command is received the FD1781 samples the Ready input. If this input is logic low the command is not executed and an interrupt is generated. The Seek or Step commands are performed regardless of the state of the Ready input.

COMMAND DESCRIPTION

The FD1781 will accept and execute eleven commands. Command words should only be loaded in the Command Register when the Busy status bit is off (Status bit 0). The one exception is the Force Interrupt command. Whenever a command is being executed, the Busy status bit is set. When a command is completed, an interrupt is generated and the Busy status bit is reset. The Status Register indicates whether the completed command encountered an error or was fault free. For ease of discussion, commands are divided into four types. Commands and types are summarized in Table 2.

TYPE I COMMANDS

The Type I Commands include the Restore, Seek, Step, Step-In, and Step-Out commands. Each of the Type I Commands contain a rate field (r_0r_1), which determines the stepping motor rate as defined in Table 1, page six.

**TABLE 2
COMMAND SUMMARY**

TYPE	COMMAND	BITS							
		7	6	5	4	3	2	1	0
I	Restore	0	0	0	0	h	V	r_1	r_0
I	Seek	0	0	0	1	h	V	r_1	r_0
I	Step	0	0	1	u	h	V	r_1	r_0
I	Step In	0	1	0	u	h	V	r_1	r_0
I	Step Out	0	1	1	u	h	V	r_1	r_0
II	Read Command	1	0	0	m	b	E	0	0
II	Write Command	1	0	1	m	b	E	X	a_0
III	Read Address	1	1	0	0	0	1	0	0
III	Read Track	1	1	1	0	0	1	0	$\bar{0}$
III	Write Track	1	1	1	1	0	1	0	0
IV	Force Interrupt	1	1	0	1	l_3	l_2	l_1	l_0

X = Don't care

**TABLE 3
FLAG SUMMARY**

TYPE I
<u>h = Head Load Flag (Bit 3)</u> h = 1, Load head at beginning h = 0, Do not load head at beginning
<u>V = Verify flag (Bit 2)</u> V = 1, Verify on last track V = 0, No verify
<u>r_1r_0 = Stepping motor rate (Bits 1-0)</u> Refer to Table 1 for rate summary
<u>u = Update flag (Bit 4)</u> u = 1, Update Track register u = 0, No update

**TABLE 4
FLAG SUMMARY**

TYPE II
<u>m = Multiple Record flag (Bit 4)</u> m = 0, Single Record m = 1, Multiple Records
<u>b = Block length flag (Bit 3)</u> b = 1, IBM format (128 to 1024 bytes) b = 0, Non-IBM format (16 to 4096 bytes)
<u>a_0 = Data Address Mark (Bit 0)</u> a_0 = 0, FB (Data Mark) a_0 = 1, F8 (Deleted Data Mark)

TABLE 5
FLAG SUMMARY

TYPE III
s = Synchronize flag (Bit 0)
$\bar{s} = 0$, Synchronize to AM
$\bar{s} = 1$, Do Not Synchronize to AM
TYPE IV
li = Interrupt Condition flags (Bits 3-0)
l0 = 1, Not Ready to Ready Transition
l1 = 1, Ready to Not Ready Transition
l2 = 1, Index Pulse
l3 = 1, Immediate interrupt
E = Enable HLD and 10 msec Delay
E = 1, Enable HLD, HLT and 15 msec Delay
E = 0, Head is assumed Engaged and there is no 15 msec Delay

The Type I Commands contain a head load flag (h) which determines if the head is to be loaded at the beginning of the command. If $h = 1$, the head is loaded at the beginning of the command (HLD output is made active). If $h = 0$, HLD is deactivated. Once the head is loaded, the head will remain engaged until the FD1781 receives a command that specifically disengages the head. If the FD1781 does not receive any commands after two revolutions of the disk, the head will be automatically disengaged (HLD made inactive). The Head Load Timing Input is sampled after a 15 ms delay, when reading or writing on the disk is to occur.

The Type I Commands also contain a verification (V) flag which determines if a verification operation is to take place on the destination track. If $V = 1$, a verification is performed, if $V = 0$, no verification is performed.

During verification, the head is loaded and after an internal 15 ms delay, the HLT input is sampled. When HLT is active (logic true), the first encountered ID field is read off the disk. The track address of the ID field is then compared to the Track Register; if there is a match and a valid ID CRC, the verification is complete, an interrupt is generated and the Busy status bit is reset. If there is not a match but there is valid ID CRC, an interrupt is generated, the Seek Error status bit (Status bit 4) is set and the Busy status bit is reset. If there is a match but not a valid CRC, the CRC error status bit is set (Status bit 3), and the next encountered ID field is read from the disk for the verification operation. If an ID field with a valid CRC cannot be found after four revolutions of the disk, the FD1781 terminates the operation and sends an interrupt, (INTRQ).

The Step, Step-In, and Step-Out commands contain an Update flag (U). When $U = 1$, the track register is updated by one for each step. When $U = 0$, the track register is not updated.

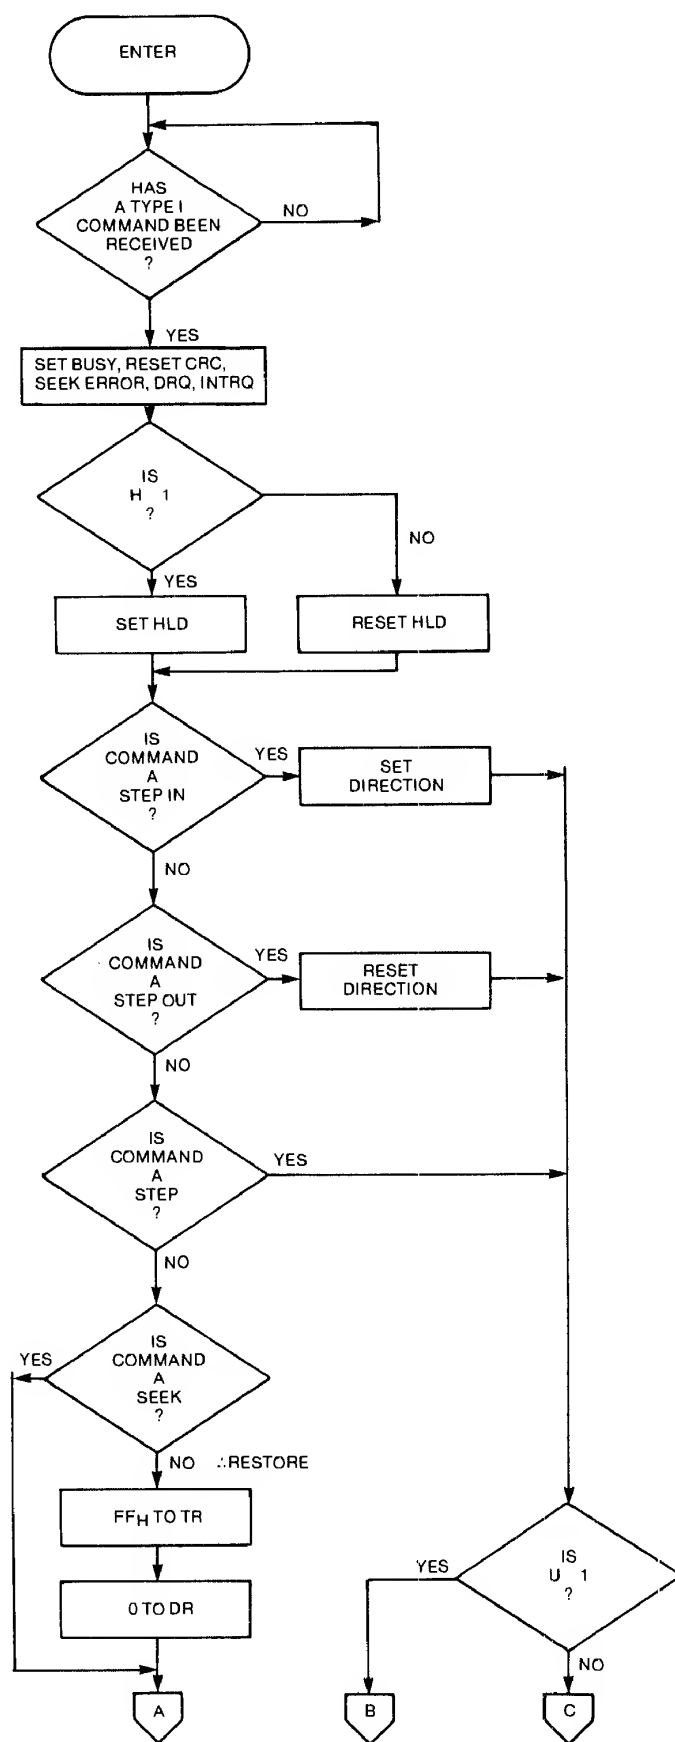

Figure 4. TYPE I COMMAND FLOW

RESTORE (SEEK TRACK 0)

Upon receipt of this command the Track 00 ($\overline{TR00}$) input is sampled. If $\overline{TR00}$ is active low indicating the Read-Write head is positioned over track 0, the Track Register is loaded with zeroes and an interrupt is generated. If $\overline{TR00}$ is not active low, stepping pulses (pins 15 to 16) at a rate specified by the $r1r0r$ field are issued until the $\overline{TR00}$ input is activated. At this time the TR is loaded with zeroes and an interrupt is generated. If the $\overline{TR00}$ input does not go active low after 255 stepping pulses, the FD1781 terminates operation, interrupts, and sets the Seek error status bit. Note that the Restore command is executed when MR goes from an active to an inactive state. A verification operation takes place if the V flag is set. The h bit allows the head to be loaded at the start of command.

SEEK

This command assumes that the Track Register contains the track number of the current position of the Read-Write head and the Data Register contains the desired track number. The FD1781 will update the Track register and issue stepping pulses in the appropriate direction until the contents of the Track register are equal to the contents of the data register (the desired track location). A verification operation takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP

Upon receipt of this command, the FD1781 issues one stepping pulse to the disk drive. The stepping motor direction is the same as in the previous step command. After a delay determined by the $r1r0$ field, a verification takes place if the V flag is on. If the u flag is on, the TR is updated. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP-IN

Upon receipt of this command, the FD1781 issues one stepping pulse in the direction towards track 76. If the u flag is on, the Track Register is incremented by one. After a delay determined by the $r1r0$ field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP-OUT

Upon receipt of this command, the FD1781 issues one stepping pulse in the direction towards track 0. If

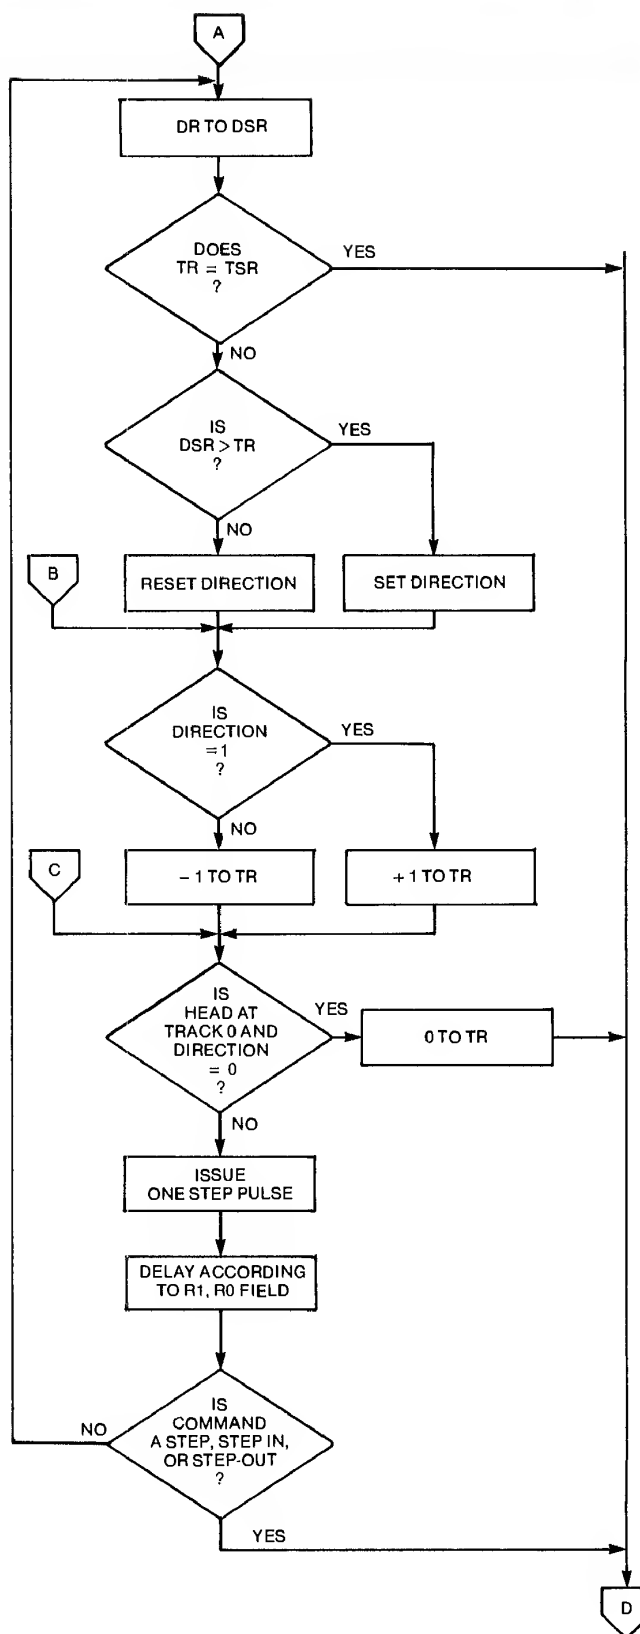

Figure 5. TYPE I COMMAND FLOW

the u flag is on, the TR is decremented by one. After a delay determined by the r1r0 field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

TYPE II COMMANDS

The Type II Commands include the Read Sector (s) and Write Sector (s) commands. Prior to loading the Type II Command into the Command Register, the computer must load the Sector Register with the desired sector number. Upon receipt of the Type II Command, the busy status Bit is set. If the E flag = 1 (this is the normal case) HLD is made active and HLT is sampled after a 15 msec delay. If the E flag is 0, the head is assumed to be engaged and there is no 15 msec delay. The ID field and Data Field format are shown on page 11.

When an ID field is located on the disk, the FD1781 compares the Track Number of the ID field with the Track Register. If there is not a match, the next encountered ID field is read and a comparison is again made. If there was a match, the Sector Number of the ID field is compared with the Sector Register. If there is not a Sector match, the next encountered ID field is read off the disk and comparisons again made. If the ID field CRC is correct, the data field is then located and will be either written into, or read from depending upon the command. The FD1781 must find an ID field with a Track number, Sector number, and CRC within four revolutions of the disk; otherwise, the Record not found status bit is set (Status bit 3) and the command is terminated with an interrupt.

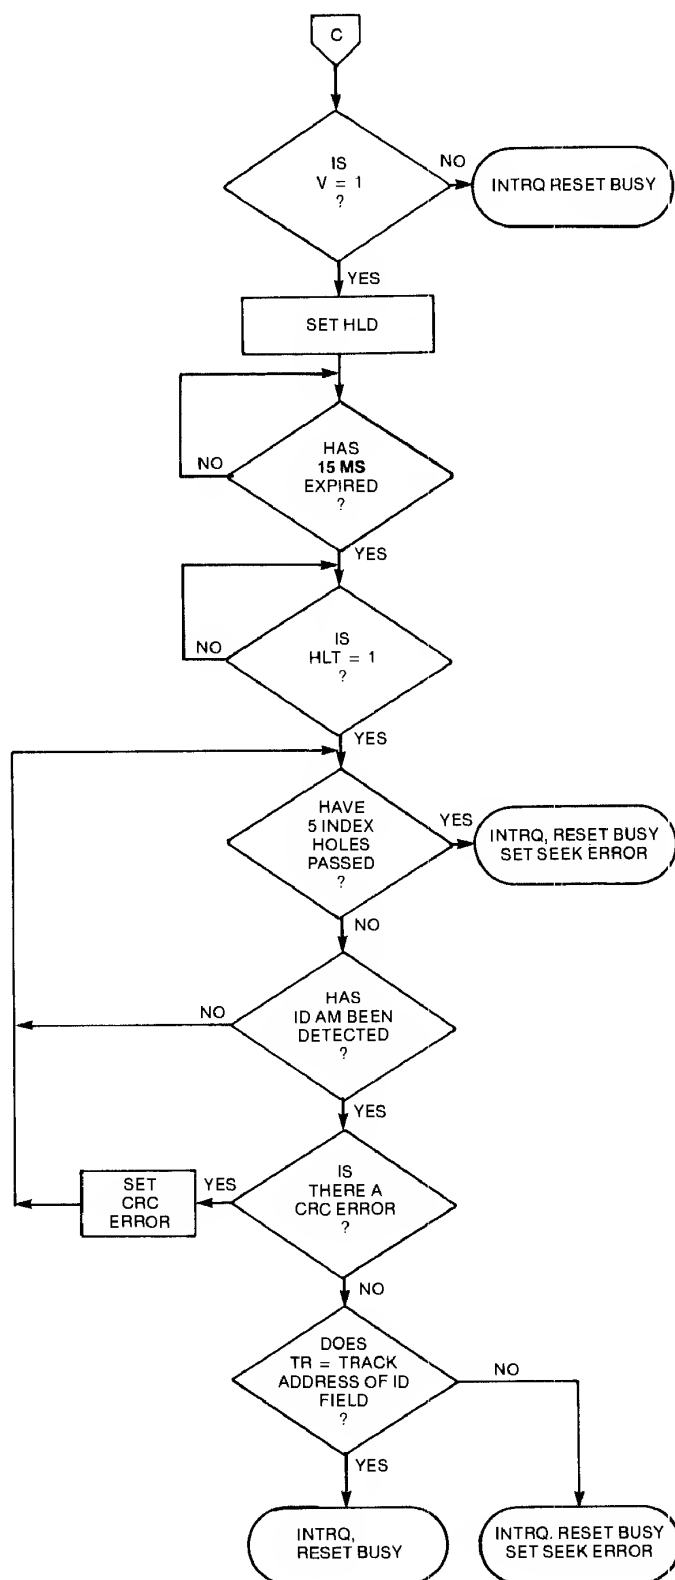

Each of the Type II Commands contain a (b) flag which in conjunction with the sector length field contents of the ID determines the length (number of characters) of the Data field.

For IBM 3740 compatibility, the b flag should equal 1. The numbers of bytes in the data field (sector) is then 128×2^n where $n = 0, 1, 2, 3$.

For $b = 1$

Sector Length Field (hex)	Number of Bytes in Sector (decimal)
00	128
01	256
02	512
03	1024

When the b flag equals zero, the sector length field (n) multiplied by 16 determines the number of bytes in the sector or data field as shown on page 11.

NOTE: IF TEST-0, THERE IS NO 15MS DELAY.
IF TEST-1 AND CLK-1 MHz. THERE IS 30MS DELAY.

Figure 6. TYPE I COMMAND FLOW

For b = 0

Sector Length Field (hex)	Number of Bytes in Sector (decimal)
01	16
02	32
03	48
04	64
•	•
•	•
•	•
FF	4080
00	4096

Each of the Type II Commands also contain a (m) flag which determines if multiple records (sectors) are to be read or written, depending upon the command. If m = 0 a single sector is read or written and an interrupt is generated at the completion of the command. If m = 1, multiple records are read or written with the sector register internally updated so that an address verification can occur on the next record. The FD1781 will continue to read or write multiple records and update the sector register until the sector register exceeds the number of sectors on the track or until the Force Interrupt command is loaded into the Command Register, which terminated the command and generates an interrupt.

READ COMMAND

Upon receipt of the Read command, the head is loaded, the Busy status bit set, and when an ID field is encountered that has the correct track number, correct sector number, and correct CRC, the data field is presented to the computer. The Data Address Mark of the data field must be found within 30 bytes in single density and 43 bytes in double density of the last ID field CRC byte; if not, the Record Not Found status bit is set and the operation is terminated.

When the first character or byte of the data field has been shifted through the DSR, it is transferred to the DR, and DRQ is generated. When the next byte is accumulated in the DSR, it is transferred to the DR and another DRQ is generated. If the Computer has not read the previous contents of the DR before a new character is transferred that character is lost and the Lost Data Status bit is set. This sequence continues until the complete data field has been inputted to the computer. If there is a CRC error at the end of the data field, the CRC error status bit is set, and the command is terminated (even if it is a multiple record command).

At the end of the Read operation, the type of Data Address Mark encountered in the data field is recorded in the Status Register (Bits 5) as shown below:

STATUS BIT 5	DATA 1	DATA 2	DATA 3
1	0	0	0
0	0	1	1

WRITE COMMAND

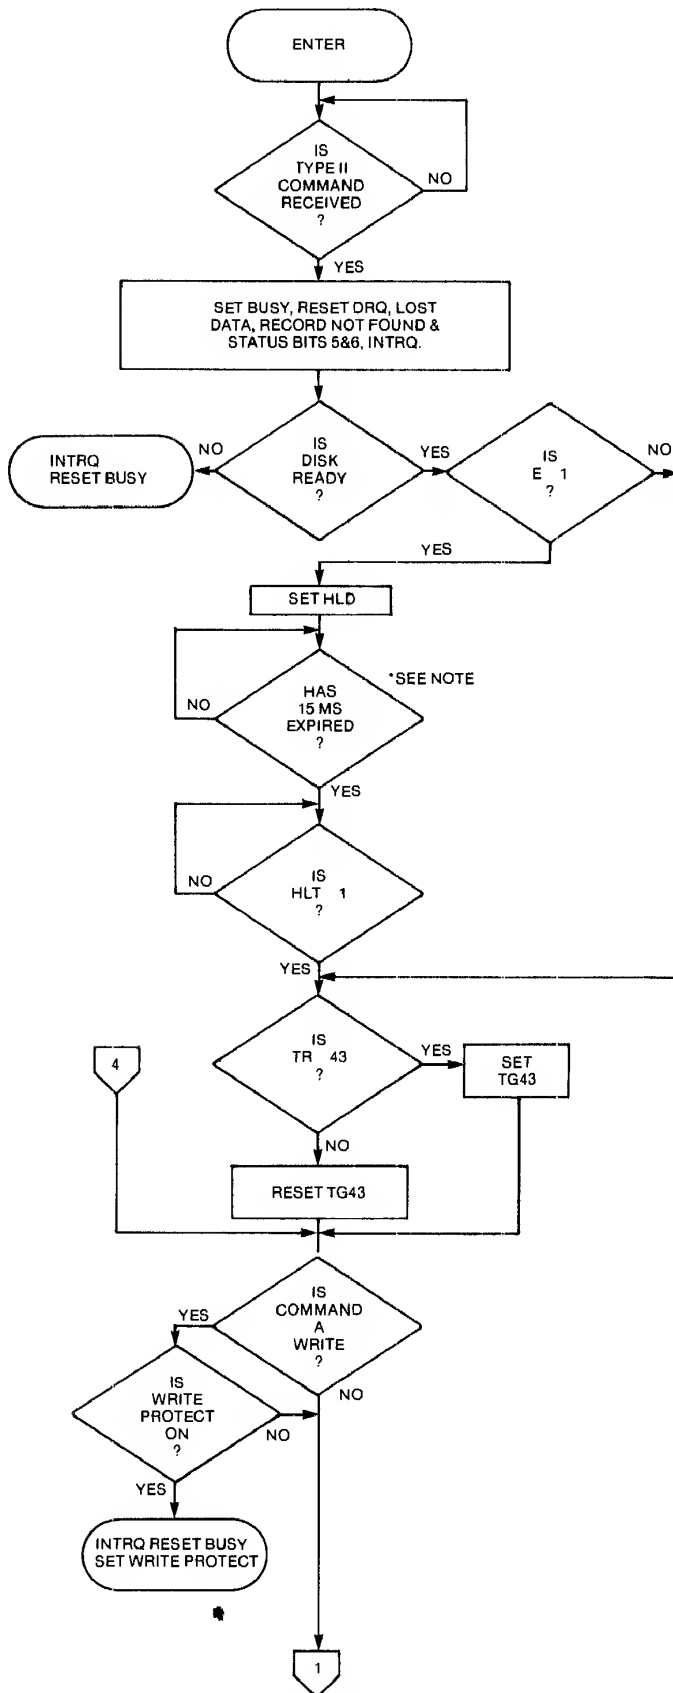

Upon receipt of the Write command, the head is loaded (HLD active) and the Busy status bit is set. When an ID field is encountered that has the correct track number, correct sector number, and correct CRC, a DRQ is generated. The FD1781 counts off 11 bytes in single density and 22 bytes in double density from the CRC field and the Write Gate (WG) output is made active if the DRQ is serviced (i.e., the DR has been loaded by the computer). If DRQ has not been serviced, the command is terminated and the Lost Data status bit is set. If the DRQ has been serviced, the WG is made active and six bytes of zeros in single density and 12 bytes in double density are then written on the disk. At this time the Data Address Mark is then written on the disk as determined by the a⁰ field of the command as shown below:

a ⁰	DATA 1	DATA 2	DATA 3
1	0	0	0
0	0	1	1

The FD1781 then writes the data field and generates DRQ's to the computer. If the DRQ is not serviced in time for continuous writing the Lost Data Status Bit is set and a byte of zeros is written on the disk. The command is not terminated. After the last data byte has been written on the disk, the two-byte CRC is computed internally and written on the disk followed by one byte gap of logic ones. The WG output is then deactivated.

GAP	ID AM	TRACK NUMBER	ZEROS	SECTOR NUMBER	SECTOR LENGTH	CRC 1	CRC 2	GAP	DATA AM	DATA FIELD	1	2
ID FIELD									DATA FIELD			

IDAM = ID Address Mark - DATA = (FE)₁₆ CLK = (C7)₁₆
 Data AM = Data Address Mark - DATA = (F8 or FB), CLK = (C7)₁₆

*NOTE: IF TEST-0, THERE IS NO 15MS DELAY.
IF TEST-1 AND CLK-1 MHz. THIS IS A 30MS DELAY.

Figure 11. TYPE III COMMAND WRITE TRACK

TYPE III COMMANDS

READ ADDRESS

Upon receipt of the Read Address command, the head is loaded and the Busy Status Bit is set. The next encountered ID field is then read in from the disk, and the six data bytes of the ID field are assembled and transferred to the DR, and a DRQ is generated for each byte. The six bytes of the ID field are shown below:

TRACK ADDR	ZEROS	SECTOR ADDRESS	SECTOR LENGTH	CRC 1	CRC 2
1	2	3	4	5	6

Although the CRC characters are transferred to the computer, the FD1781 checks for validity and the CRC error status bit is set if there is a CRC error. The Track Address of the ID field is written into the sector register. At the end of the operation an interrupt is generated and the Busy Status is reset.

READ TRACK

Upon receipt of the Read Track command, the head is loaded and the Busy Status bit is set. Reading starts with the leading edge of the first encountered index mark and continues until the next index pulse.

As each byte is assembled it is transferred to the Data Register and the Data Request is generated for each byte. No CRC checking is performed. Gaps are included in the input data stream. If bit 0 (S) of the command is a 0, the accumulation of bytes is synchronized to each Address Mark encountered. Upon completion of the command, the interrupt is activated.

WRITE TRACK

Upon receipt of the Write Track command, the head is loaded and the Busy Status bit is set. Writing starts with the leading edge of the first encountered index pulse and continues until the next index pulse, at which time the interrupt is activated. The Data Request is activated immediately upon receiving the command, but writing will not start until after the first byte has been loaded into the Data Register. If the DR has not been loaded by the time the index pulse is encountered the operation is terminated making the device Not Busy, the Lost Data Status Bit is set, and the Interrupt is activated. If a byte is not present in the DR when needed, a byte of zeros is substituted. Address marks and CRC characters are written on the disk by detecting certain data byte patterns in the outgoing data stream as shown in the table below. The CRC generator is initialized when any data byte from F8 to FE is about to be transferred from the DR to the DSR.

CONTROL BYTES FOR INITIALIZATION

DATA PATTERN (HEX)	INTERPRETATION	CLOCK MARK* (HEX)
F7	Write CRC Char.	FF
F8	Deleted Data Addr. Mark	C7
FB	Data Addr. Mark	C7
FC	Index Addr. Mark	D7
FD	Spare	
FE	ID Addr. Mark	C7

*Single density only

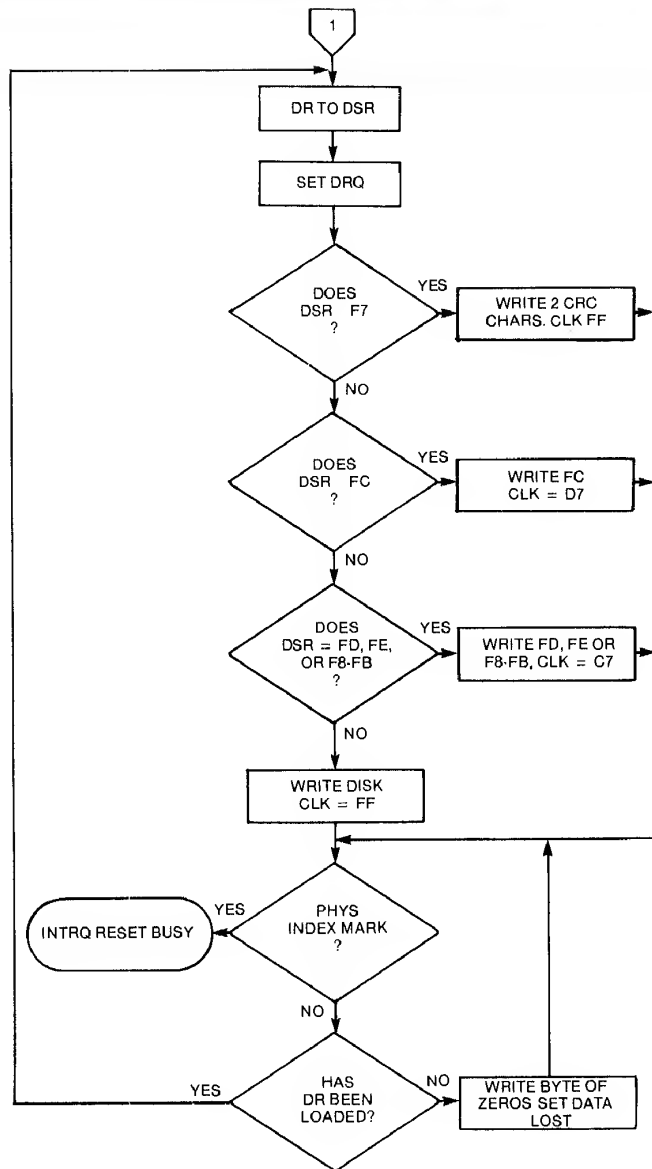

Figure 12. TYPE III COMMAND WRITE TRACK

DATA 1	DATA 2	DATA 3	TYPE OF ADDRESS MARK
0	0	0	Deleted Data Mark
0	1	1	Data Mark
1	0	0	Index Address Mark
1	0	1	Undefined
1	1	0	ID Address Mark
1	1	1	Undefined

TYPE IV COMMAND**FORCE INTERRUPT**

This command can be loaded into the command register at any time. If there is a current command under execution (Busy Status Bit set), the command will be terminated and an interrupt will be generated when the condition specified in the I₀ through I₃ field is detected. The interrupt conditions are shown below:

- I₀ = Not-Ready-To-Ready Transition
- I₁ = Ready-To-Not-Ready Transition
- I₂ = Every Index Pulse
- I₃ = Immediate Interrupt

NOTE: If I₀-I₃ = 0, there is no interrupt generated but the current command is terminated and busy is reset.

STATUS DESCRIPTION

Upon receipt of any command, except the Force Interrupt command, the Busy Status bit is set and the rest of the status bits are updated or cleared for the new command. If the Force Interrupt Command is received when there is a current command under execution, the Busy status bit is reset, and the rest of the status bits are unchanged. If the Force Interrupt command is received when there is not a current command under execution, the Busy Status bit is reset and the rest of the status bits are updated or cleared. In this case, Status reflects the Type I commands.

The format of the Status Register is shown below:

7	6	5	4	3	2	1	0
S7	S6	S5	S4	S3	S2	S1	S0

Status varies according to the type of command executed as shown in Table 6.

TABLE 6
STATUS REGISTER SUMMARY

BIT	ALL TYPE I COMMANDS	READ ADDRESS	READ	READ TRACK	WRITE	WRITE TRACK
S7	NOT READY	NOT READY	NOT READY	NOT READY	NOT READY	NOT READY
S6	WRITE PROTECT	0	0	0	WRITE PROTECT	WRITE PROTECT
S5	HEAD ENGAGED	0	RECORD TYPE	0	WRITE FAULT	WRITE FAULT
S4	SEEK ERROR	ID NOT FOUND	RECORD NOT FOUND	0	RECORD NOT FOUND	0
S3	CRC ERROR	CRC ERROR	CRC ERROR	0	CRC ERROR	0
S2	TRACK 0	LOST DATA	LOST DATA	LOST DATA	LOST DATA	LOST DATA
S1	INDEX	DRQ	DRQ	DRQ	DRQ	DRQ
S0	BUSY	BUSY	BUSY	BUSY	BUSY	BUSY

STATUS FOR TYPE I COMMANDS

BIT NAME	MEANING
S7 NOT READY	This bit when set indicates the drive is not ready. When reset it indicates that the drive is ready. This bit is an inverted copy of the Ready input and logically 'ored' with MR.
S6 PROTECTED	When set, indicates Write Protect is activated. This bit is an inverted copy of \overline{WRPT} input.
S5 HEAD LOADED	When set, it indicates the head is loaded and engaged. This bit is a logical "and" of HLD and HLT signals.
S4 SEEK ERROR	When set, the desired track was not verified. This bit is reset to 0 when updated.
S3 CRC ERROR	When set, there was one or more CRC errors encountered on an unsuccessful track verification operation. This bit is reset to 0 when updated.
S2 TRACK 00	When set, indicates Read Write head is positioned to Track 0. This bit is an inverted copy of the $\overline{TR00}$ input.
S1 INDEX	When set, indicates index mark detected from drive. This bit is an inverted copy of the \overline{IP} input.
S0 BUSY	When set command is in progress. When reset no command is in progress.

STATUS BITS FOR TYPE II AND TYPE III COMMANDS

BIT NAME	MEANING
S7 NOT READY	This bit when set indicates the drive is not ready. When reset, it indicates that the drive is ready. This bit is an inverted copy of the Ready input and 'ored' with MR. The Type II and III Commands will not execute unless the drive is ready.
S6 WRITE PROTECT	On Read Record: Not Used. On Read Track: Not Used. On any Write: It indicates a Write Protect. This bit is reset when updated.
S5 RECORD TYPE/ WRITE FAULT	On Read Record: It indicates the record-type code from data field address mark. On Read Track: Not Used. On any Write: It indicates a Write Fault. This bit is reset when updated.
S4 RECORD NOT FOUND	When set, it indicates that the desired track and sector were not found. This bit is reset when updated.
S3 CRC ERROR	If S4 is set, an error is found in one or more ID fields; otherwise it indicates error in data field. This bit is reset when updated.
S2 LOST DATA	When set, it indicates the computer did not respond to DRQ in one byte time. This bit is reset to zero when updated.
S1 DATA REQUEST	This bit is a copy of the DRQ output. When set, it indicates the DR is full on a Read operation or the DR is empty on a Write operation. This bit is reset to zero when updated.
S0 BUSY	When set, command is under execution. When reset, no command is under execution.

FORMATTING THE DISK

(Refer to section on Type III commands for flow diagrams.)

Formatting the disk is a relatively simple task when operating programmed I/O or when operating under DMA control with a large amount of memory. When operating under DMA with limited amount of memory, formatting is a more difficult task. This is because gaps as well as data must be provided at the computer interface.

Formatting the disk is accomplished by positioning the R/W head over the desired track number and issuing the Write Track command. Upon receipt of the Write Track command, the FD1781 raises the data request signal. At this point in time, the user loads the data register with desired data to be written on the disk. For every byte of information to be written on the disk, a data request is generated. This sequence continues from one index mark to the next index mark. Normally, whatever data pattern appears in the data register is written on the disk with a clock mark of (FF)16. However, if the FD1781 detects a data pattern on F7 thru FE in the data register, this is interpreted as data address marks with missing clocks or CRC generation. For instance, an FE pattern will be interpreted as an ID address mark (DATA-FE, CLK-C7) and the CRC will be initialized. An F7 pattern will generate two CRC characters. As a consequence, the patterns F7 thru FE must not appear in the gaps, data fields, or ID fields. Also, CRC's must be generated by a F7 pattern.

Disks may be formatted in IBM 3740 formats with sector lengths of 128, 256, 512, or 1024 bytes, or may be formatted in non-IBM 3740 with sectors length of 16 to 4096 bytes in 16 byte increments. IBM 3740 at

the present time only defines two formats. One format with 128 bytes/sector and the other with 256 bytes/sector. The next section deals with the IBM 3740 format with 128 bytes/sector and the following section details non-IBM formats.

IBM 3740 FORMATS — 128 BYTES/SECTOR

Shown in Figure 13, is the IBM format with 128 bytes/sector. In order to format this format, the user must issue the Write Track command, and load the data register with the following values. For every byte to be written, there is one data request.

NUMBER OF BYTES	HEX VALUE OF BYTE WRITTEN
40	00 or FF
6	00
1	FC (Index Mark)
26	00 or FF
* 6	00
1	FE (ID Address Mark)
1	Track Number
1	00
1	Sector Number (1 thru 1A)
1	00
1	F7 (2 CRC's written)
11	00 or FF
6	00
1	FB (Data Address Mark)
128	Data (IBM uses E5)
1	F7 (2 CRC's written)
27	00 or FF
247**	00 or FF

*Write bracketed field 26 times

**Continue writing until FD1781 interrupts out. Approx. 247 bytes.

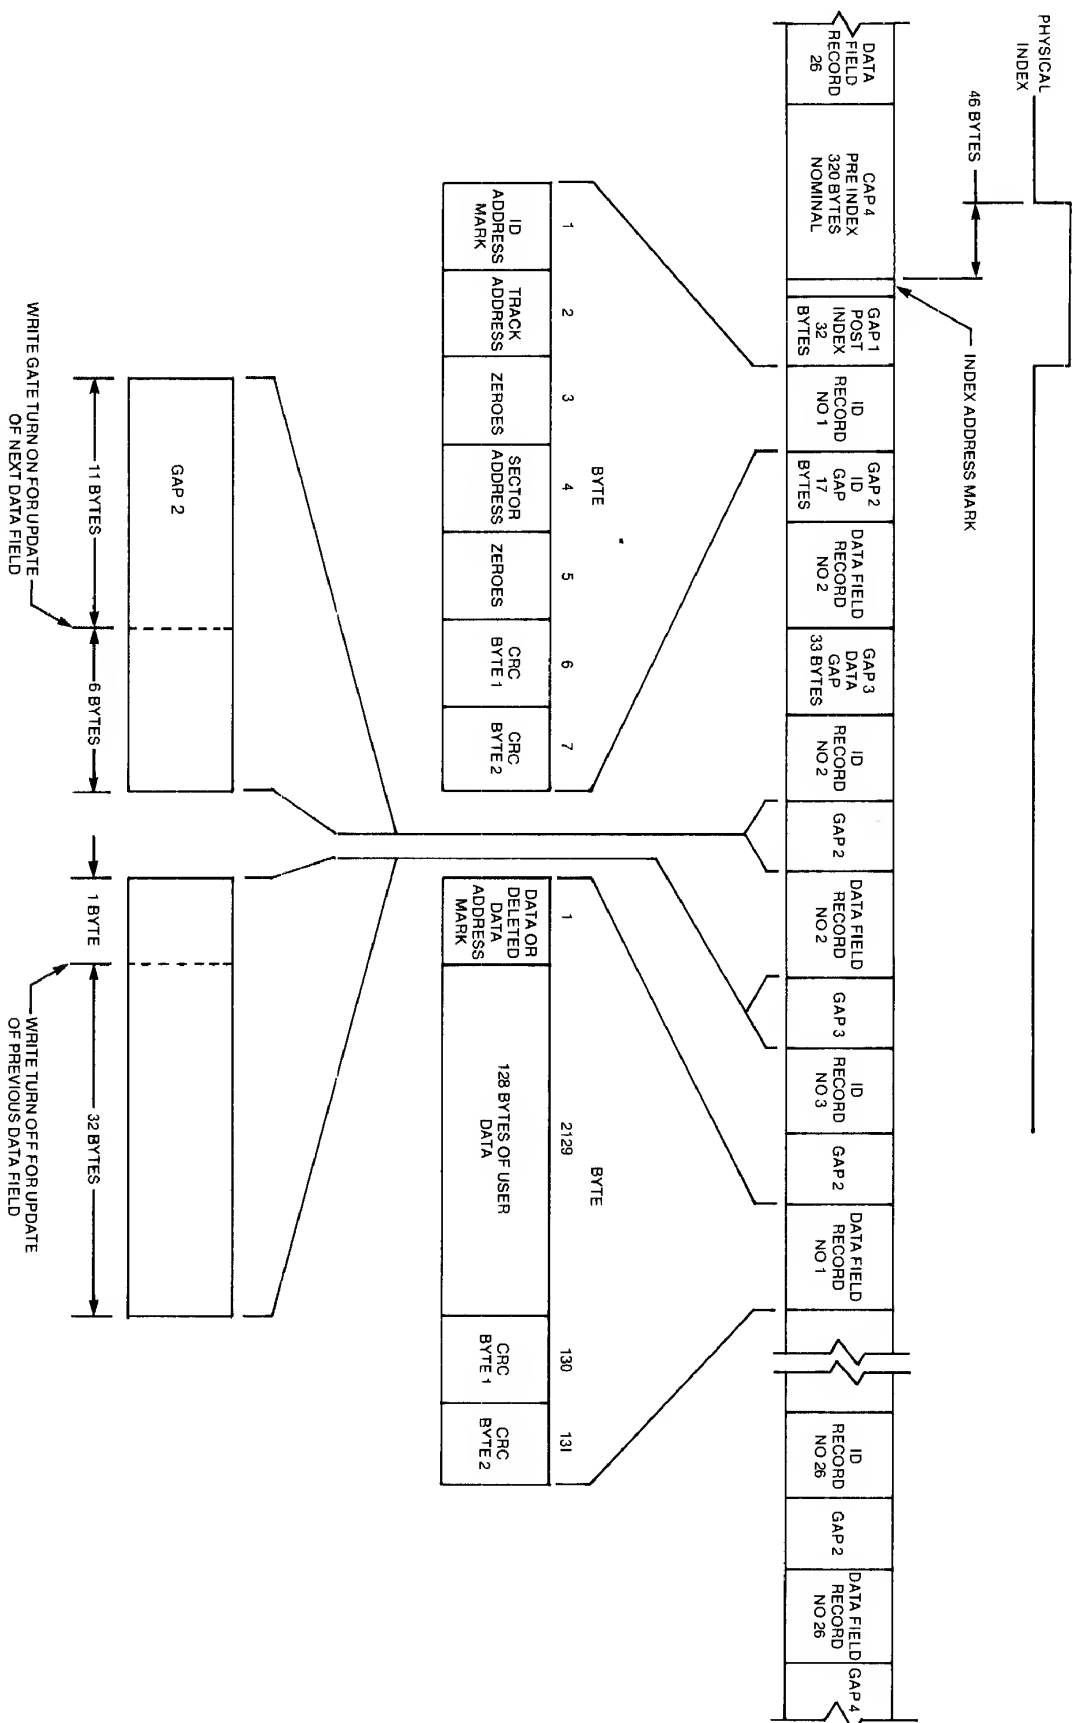

Figure 13. IBM 3740 TRACK FORMAT

NON-IBM FORMATS

Non-IBM formats are very similar to the IBM formats except a different algorithm is used to ascertain the sector length from the sector length byte in the ID field. This permits a wide range of sector lengths from 16 to 4096 bytes. Refer to Section V, Type II Commands with b flag equal to zero. Note that F7 thru FE must not appear in the sector length byte of the ID field.

In formatting the FD1781, only two requirements regarding GAP sizes must be met. GAP 2 (i.e., the gap between the ID field and data field) must be 17 bytes of which the last 6 bytes must be zeros in single density mode, and 34 bytes of which the last 12 bytes must be zeros in double density mode. For the FD1781-01, these byte counts for GAP2 are doubled.

The FD1781 does not require the index address mark (i.e., DATA = FC, CLK = D7) and it need not be present.

FD179X-02

Floppy Disk Formatter/Controller Family

FD179X-02

FEATURES

- TWO VFO CONTROL SIGNALS — RG & VFOE
- SOFT SECTOR FORMAT COMPATIBILITY
- AUTOMATIC TRACK SEEK WITH VERIFICATION
- ACCOMMODATES SINGLE AND DOUBLE DENSITY FORMATS
 - IBM 3740 Single Density (FM)
 - IBM System 34 Double Density (MFM)
 - Non IBM Format for Increased Capacity
- READ MODE
 - Single/Multiple Sector Read with Automatic Search or Entire Track Read
 - Selectable 128, 256, 512 or 1024 Byte Sector Lengths
- WRITE MODE
 - Single/Multiple Sector Write with Automatic Sector Search
 - Entire Track Write for Diskette Formatting
- SYSTEM COMPATIBILITY
 - Double Buffering of Data 8 Bit Bi-Directional Bus for Data, Control and Status
 - DMA or Programmed Data Transfers
 - All Inputs and Outputs are TTL Compatible
 - On-Chip Track and Sector Registers/Comprehensive Status Information

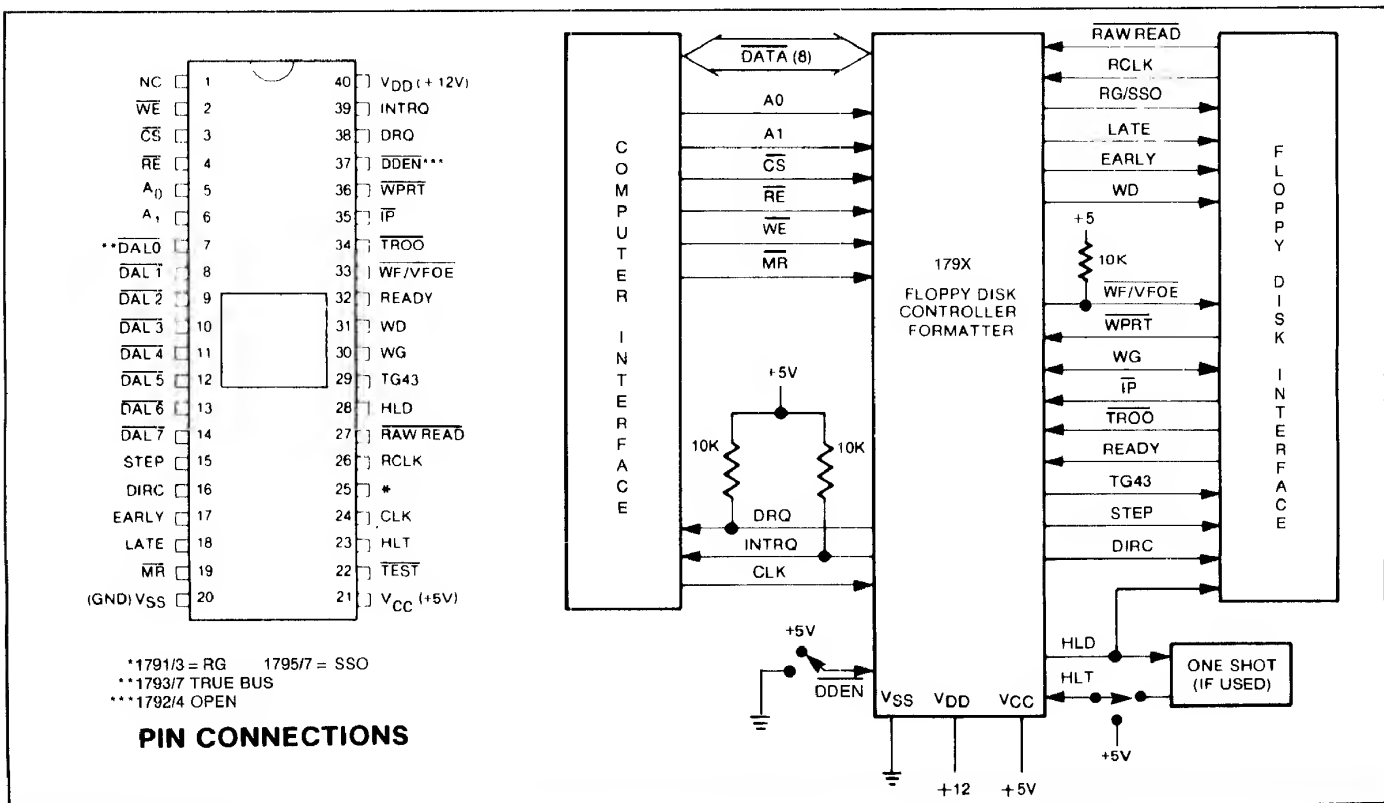

- PROGRAMMABLE CONTROLS
 - Selectable Track to Track Stepping Time
 - Side Select Compare
- INTERFACES TO WD1691 DATA SEPARATOR
- WINDOW EXTENSION
- INCORPORATES ENCODING/DECODING AND ADDRESS MARK CIRCUITRY
- FD1792/4 IS SINGLE DENSITY ONLY
- FD1795/7 HAS A SIDE SELECT OUTPUT

PIN OUTS

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION																									
1	NO CONNECTION	NC	Pin 1 is internally connected to a back bias generator and must be left open by the user.																									
19	MASTER RESET	MR	A logic low (50 microseconds min.) on this input resets the device and loads HEX 03 into the command register. The Not Ready (Status Bit 7) is reset during MR ACTIVE. When MR is brought to a logic high a RESTORE Command is executed, regardless of the state of the Ready signal from the drive. Also, HEX 01 is loaded into sector register.																									
20	POWER SUPPLIES	Vss	Ground																									
21		Vcc	+5V ± 5%																									
40		Vdd	+12V ± 5%																									
COMPUTER INTERFACE:																												
2	WRITE ENABLE	WE	A logic low on this input gates data on the DAL into the selected register when CS is low.																									
3	CHIP SELECT	CS	A logic low on this input selects the chip and enables computer communication with the device.																									
4	READ ENABLE	RE	A logic low on this input controls the placement of data from a selected register on the DAL when CS is low.																									
5,6	REGISTER SELECT LINES	A0, A1	These inputs select the register to receive/transfer data on the DAL lines under RE and WE control: <table><tr><td>CS</td><td>A1</td><td>A0</td><td>RE</td><td>WE</td></tr><tr><td>0</td><td>0</td><td>0</td><td>Status Reg</td><td>Command Reg</td></tr><tr><td>0</td><td>0</td><td>1</td><td>Track Reg</td><td>Track Reg</td></tr><tr><td>0</td><td>1</td><td>0</td><td>Sector Reg</td><td>Sector Reg</td></tr><tr><td>0</td><td>1</td><td>1</td><td>Data Reg</td><td>Data Reg</td></tr></table>	CS	A1	A0	RE	WE	0	0	0	Status Reg	Command Reg	0	0	1	Track Reg	Track Reg	0	1	0	Sector Reg	Sector Reg	0	1	1	Data Reg	Data Reg
CS	A1	A0	RE	WE																								
0	0	0	Status Reg	Command Reg																								
0	0	1	Track Reg	Track Reg																								
0	1	0	Sector Reg	Sector Reg																								
0	1	1	Data Reg	Data Reg																								
7-14	DATA ACCESS LINES	DAL0-DAL7	Eight bit Bidirectional bus used for transfer of data, control, and status. This bus is receiver enabled by WE or transmitter enabled by RE. Each line will drive 1 standard TTL load.																									
24	CLOCK	CLK	This input requires a free-running 50% duty cycle square wave clock for internal timing reference, 2 MHz ± 1% for 8" drives, 1 MHz ± 1% for mini-floppies.																									
38	DATA REQUEST	DRQ	This open drain output indicates that the DR contains assembled data in Read operations, or the DR is empty in Write operations. This signal is reset when serviced by the computer through reading or loading the DR in Read or Write operations, respectively. Use 10K pull-up resistor to +5.																									
39	INTERRUPT REQUEST	INTRQ	This open drain output is set at the completion of any command and is reset when the STATUS register is read or the command register is written to. Use 10K pull-up resistor to +5.																									
FLOPPY DISK INTERFACE:																												
15	STEP	STEP	The step output contains a pulse for each step.																									
16	DIRECTION	DIRC	Direction Output is active high when stepping in, active low when stepping out.																									
17	EARLY	EARLY	Indicates that the WRITE DATA pulse occurring while Early is active (high) should be shifted early for write precompensation.																									
18	LATE	LATE	Indicates that the write data pulse occurring while Late is active (high) should be shifted late for write precompensation.																									

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
22	TEST	TEST	This input is used for testing purposes only and should be tied to +5V or left open by the user unless interfacing to voice coil actuated steppers.
23	HEAD LOAD TIMING	HLT	When a logic high is found on the HLT input the head is assumed to be engaged. It is typically derived from a 1 shot triggered by HLD.
25	READ GATE (1791, 1792, 1793, 1794)	RG	This output is used for synchronization of external data separators. The output goes high after two Bytes of zeros in single density, or 4 Bytes of either zeros or ones in double density operation.
25	SIDE SELECT OUTPUT (1795, 1797)	SSO	The logic level of the Side Select Output is directly controlled by the 'S' flag in Type II or III commands. When U = 1, SSO is set to a logic 1. When U = 0, SSO is set to a logic 0. The SSO is compared with the side information in the Sector I.D. Field. If they do not compare Status Bit 4 (RNF) is set. The Side Select Output is only updated at the beginning of a Type II or III command. It is forced to a logic 0 upon a MASTER RESET condition.
26	READ CLOCK	RCLK	A nominal square-wave clock signal derived from the data stream must be provided to this input. Phasing (i.e. RCLK transitions) relative to RAW READ is important but polarity (RCLK high or low) is not.
27	RAW READ	RAW READ	The data input signal directly from the drive. This input shall be a negative pulse for each recorded flux transition.
28	HEAD LOAD	HLD	The HLD output controls the loading of the Read-Write head against the media.
29	TRACK GREATER THAN 43	TG43	This output informs the drive that the Read/Write head is positioned between tracks 44-76. This output is valid only during Read and Write Commands.
30	WRITE GATE	WG	This output is made valid before writing is to be performed on the diskette.
31	WRITE DATA	WD	A 200 ns (MFM) or 500 ns (FM) output pulse per flux transition. WD contains the unique Address marks as well as data and clock in both FM and MFM formats.
32	READY	READY	This input Indicates disk readiness and is sampled for a logic high before Read or Write commands are performed. If Ready is low the Read or Write operation is not performed and an interrupt is generated. Type I operations are performed regardless of the state of Ready. The Ready input appears in inverted format as Status Register bit 7.
33	WRITE FAULT VFO ENABLE	WF/VFOE	This is a bi-directional signal used to signify writing faults at the drive, and to enable the external PLO data separator. When WG = 1, Pin 33 functions as a WF input. If WF = 0, any write command will immediately be terminated. When WG = 0, Pin 33 functions as a VFOE output. VFOE will go low during a read operation after the head has loaded and settled (HLT = 1). On the 1795/7, it will remain low until the last bit of the second CRC byte in the ID field. VFOE will then go high until 8 bytes (MFM) or 4 bytes (FM) before the Address Mark. It will then go active until the last bit of the second CRC byte of the Data Field. On the 1791/3, VFOE will remain low until the end of the Data Field. This pin has an internal 100K Ohm pull-up resistor.
34	TRACK 00	TR00	This input informs the FD179X that the Read/Write head is positioned over Track 00.

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
35	INDEX PULSE	IP	This input informs the FD179X when the index hole is encountered on the diskette.
36	WRITE PROTECT	WPRT	This input is sampled whenever a Write Command is received. A logic low terminates the command and sets the Write Protect Status bit.
37	DOUBLE DENSITY	DDEN	This input pin selects either single or double density operation. When $\overline{DDEN} = 0$, double density is selected. When $\overline{DDEN} = 1$, single density is selected. This line must be left open on the 1792/4.

GENERAL DESCRIPTION

The FD179X are N-Channel Silicon Gate MOS LSI devices which perform the functions of a Floppy Disk Formatter/Controller in a single chip implementation. The FD179X, which can be considered the end result of both the FD1771 and FD1781 designs, is IBM 3740 compatible in single density mode (FM) and System 34 compatible in Double Density Mode (MFM). The FD179X contains all the features of its predecessor the FD1771, plus the added features necessary to read/write and format a double density diskette. These include address mark detection, FM and MFM encode and decode logic, window extension, and write precompensation. In order to maintain compatibility, the FD1771, FD1781, and FD179X designs were made as close as possible with the computer interface, instruction set, and I/O registers being identical. Also, head load control is identical. In each case, the actual pin assignments vary by only a few pins from any one to another.

The processor interface consists of an 8-bit bi-directional bus for data, status, and control word transfers. The FD179X is set up to operate on a multiplexed bus with other bus-oriented devices.

The FD179X is TTL compatible on all inputs and outputs. The outputs will drive ONE TTL load or three LS loads. The 1793 is identical to the 1791 except the DAL lines are TRUE for systems that utilize true data busses.

The 1795/7 has a side select output for controlling double sided drives, and the 1792 and 1794 are "Single Density Only" versions of the 1791 and 1793 respectively. On these devices, DDEN must be left open.

ORGANIZATION

The Floppy Disk Formatter block diagram is illustrated on page 5. The primary sections include the parallel processor interface and the Floppy Disk interface.

Data Shift Register — This 8-bit register assembles serial data from the Read Data input (RAW READ) during Read operations and transfers serial data to the Write Data output during Write operations.

Data Register — This 8-bit register is used as a holding register during Disk Read and Write operations. In Disk Read operations the assembled data byte is transferred in parallel to the Data Register from the Data Shift Register. In Disk Write operations information is transferred in parallel from the Data Register to the Data Shift Register.

When executing the Seek command the Data Register holds the address of the desired Track position. This register is loaded from the DAL and gated onto the DAL under processor control.

Track Register — This 8-bit register holds the track number of the current Read/Write head position. It is incremented by one every time the head is stepped in (towards track 76) and decremented by one when the head is stepped out (towards track 00). The contents of the register are compared with the recorded track number in the ID field during disk Read, Write, and Verify operations. The Track Register can be loaded from or transferred to the DAL. This Register should not be loaded when the device is busy.

Sector Register (SR) — This 8-bit register holds the address of the desired sector position. The contents of the register are compared with the recorded sector number in the ID field during disk Read or Write operations. The Sector Register contents can be loaded from or transferred to the DAL. This register should not be loaded when the device is busy.

Command Register (CR) — This 8-bit register holds the command presently being executed. This register should not be loaded when the device is busy unless the new command is a force Interrupt. The command register can be loaded from the DAL, but not read onto the DAL.

Status Register (STR) — This 8-bit register holds device Status information. The meaning of the Status bits is a function of the type of command previously executed. This register can be read onto the DAL, but not loaded from the DAL.

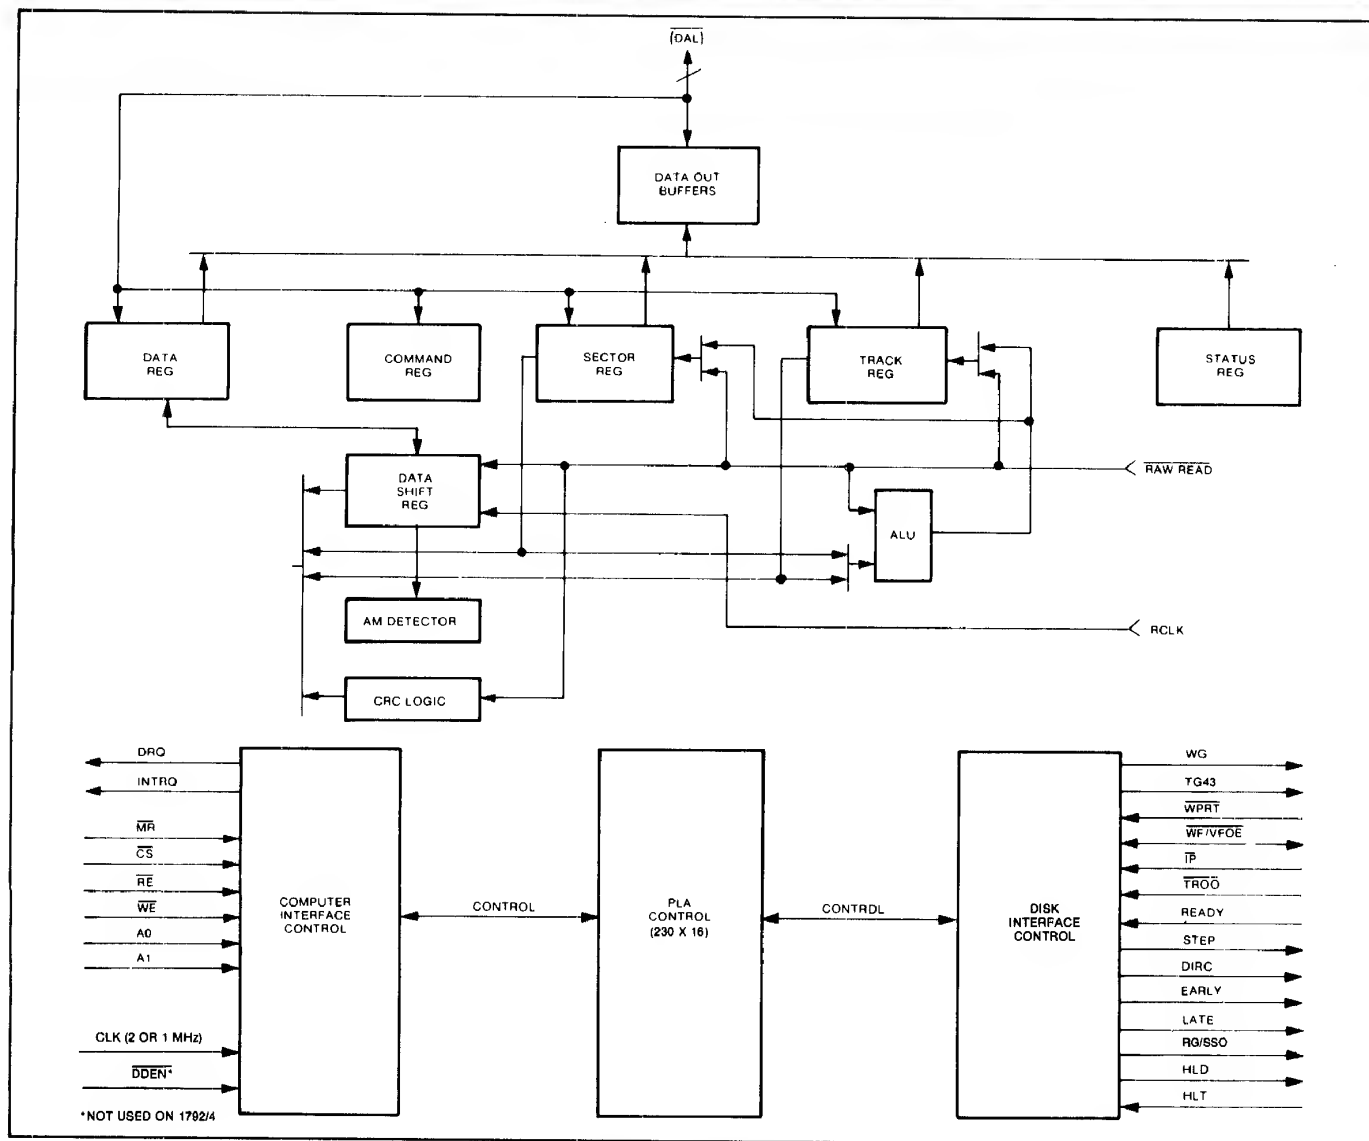

CRC Logic — This logic is used to check or to generate the 16-bit Cyclic Redundancy Check (CRC). The polynomial is: $G(x) = x^{16} + x^{12} + x^5 + 1$.

The CRC includes all information starting with the address mark and up to the CRC characters. The CRC register is preset to ones prior to data being shifted through the circuit.

Arithmetic/Logic Unit (ALU) — The ALU is a serial comparator, incrementer, and decrements and is used for register modification and comparisons with the disk recorded ID field.

Timing and Control — All computer and Floppy Disk Interface controls are generated through this logic. The internal device timing is generated from an external crystal clock.

The FD179X has two different modes of operation according to the state of DDEN. When $\overline{DDEN} = 0$ double density (MFM) is assumed. When $\overline{DDEN} = 1$, single

FD179X BLOCK DIAGRAM

density (FM) is assumed. 1792 & 1794 are single density only.

AM Detector — The address mark detector detects ID, data and index address marks during read and write operations.

PROCESSOR INTERFACE

The interface to the processor is accomplished through the eight Data Access Lines (DAL) and associated control signals. The DAL are used to transfer Data, Status, and Control words out of, or into the FD179X. The DAL are three state buffers that are enabled as output drivers when Chip Select (CS) and Read Enable (RE) are active (low logic state) or act as input receivers when CS and Write Enable (WE) are active.

When transfer of data with the Floppy Disk Controller is required by the host processor, the device address is decoded and CS is made low. The address bits A1 and A0, combined with the signals RE during a Read operation or WE during a Write operation are interpreted as selecting the following registers:

A1 - A0	READ (RE)	WRITE (WE)
0 0	Status Register	Command Register
0 1	Track Register	Track Register
1 0	Sector Register	Sector Register
1 1	Data Register	Data Register

During Direct Memory Access (DMA) types of data transfers between the Data Register of the FD179X and the processor, the Data Request (DRQ) output is used in Data Transfer control. This signal also appears as status bit 1 during Read and Write operations.

On Disk Read operations the Data Request is activated (set high) when an assembled serial input byte is transferred in parallel to the Data Register. This bit is cleared when the Data Register is read by the processor. If the Data Register is read after one or more characters are lost, by having new data transferred into the register prior to processor readout, the Lost Data bit is set in the Status Register. The Read operation continues until the end of sector is reached.

On Disk Write operations the data Request is activated when the Data Register transfers its contents to the Data

Shift Register, and requires a new data byte. It is reset when the Data Register is loaded with new data by the processor. If new data is not loaded at the time the next serial byte is required by the Floppy Disk, a byte of zeroes is written on the diskette and the Lost Data bit is set in the Status Register.

At the completion of every command an INTRQ is generated. INTRQ is reset by either reading the status register or by loading the command register with a new command. In addition, INTRQ is generated if a Force Interrupt command condition is met.

The 179X has two modes of operation according to the state of $\overline{\text{DDEN}}$ (Pin 37). When $\overline{\text{DDEN}} = 1$, single density is selected. In either case, the CLK input (Pin 24) is at 2 MHz. However, when interfacing with the mini-floppy, the CLK input is set at 1 MHz for both single density and double density.

GENERAL DISK READ OPERATIONS

Sector lengths of 128, 256, 512 or 1024 are obtainable in either FM or MFM formats. For FM, $\overline{\text{DDEN}}$ should be placed to logical "1." For MFM formats, $\overline{\text{DDEN}}$ should be placed to a logical "0." Sector lengths are determined at format time by the fourth byte in the "ID" field.

Sector Length Table*	
Sector Length Field (hex)	Number of Bytes in Sector (decimal)
00	128
01	256
02	512
03	1024

*1795/97 may vary — see command summary.

The number of sectors per track as far as the FD179X is concerned can be from 1 to 255 sectors. The number of tracks as far as the FD179X is concerned is from 0 to 255 tracks. For IBM 3740 compatibility, sector lengths are 128 bytes with 26 sectors per track. For System 34 compatibility (MFM), sector lengths are 256 bytes/sector with 26 sectors/track; or lengths of 1024 bytes/sector with 8 sectors/track. (See Sector Length Table)

For read operations in 8" double density the FD179X requires $\overline{\text{RAW READ}}$ Data (Pin 27) signal which is a 200 ns pulse per flux transition and a Read clock (RCLK) signal to indicate flux transition spacings. The RCLK (Pin 26) signal is provided by some drives but if not it may be derived externally by Phase lock loops, one shots, or counter techniques. In addition, a Read Gate Signal is provided as an output (Pin 25) on 1791/92/93/94 which can be used to inform phase lock loops when to acquire synchronization. When reading from the media in FM, RG is made true when 2 bytes of zeroes are detected. The FD179X must find an address mark within the next 10 bytes; otherwise RG is reset and the search for 2 bytes of zeroes begins all over again. If an address mark is found within 10 bytes, RG remains true as long as the FD179X is deriving any useful information from the data stream. Similarly for MFM, RG is made active when 4 bytes of "00" or "FF" are detected. The FD179X must find an address mark within the next 16 bytes, otherwise RG is reset and search resumes.

During read operations ($\text{WG} = 0$), the $\overline{\text{VFOE}}$ (Pin 33) is provided for phase lock loop synchronization. $\overline{\text{VFOE}}$ will go active low when:

- Both HLT and HLD are True
- Settling Time, if programmed, has expired
- The 179X is inspecting data off the disk

If $\overline{\text{WF/VFOE}}$ is not used, leave open or tie to a 10K resistor to +5.

GENERAL DISK WRITE OPERATION

When writing is to take place on the diskette the Write Gate (WG) output is activated, allowing current to flow into the Read/Write head. As a precaution to erroneous writing the first data byte must be loaded into the Data Register in response to a Data Request from the FD179X before the Write Gate signal can be activated.

Writing is inhibited when the Write Protect input is a logic low, in which case any Write command is immediately terminated, an interrupt is generated and the Write Protect status bit is set. The Write Fault input, when activated, signifies a writing fault condition detected in disk drive electronics such as failure to detect write current flow when the Write Gate is activated. On detection of this fault the FD179X terminates the current command, and sets the Write Fault bit (bit 5) in the Status Word. The Write Fault input should be made inactive when the Write Gate output becomes inactive.

For write operations, the FD179X provides Write Gate (Pin 30) and Write Data (Pin 31) outputs. Write data consists of a series of 500 ns pulses in FM ($\overline{\text{DDEN}} = 1$) and 200 ns pulses in MFM ($\overline{\text{DDEN}} = 0$). Write Data provides the unique address marks in both formats.

Also during write, two additional signals are provided for write precompensation. These are EARLY (Pin 17) and LATE (Pin 18). EARLY is active true when the WD pulse appearing on (Pin 30) is to be written EARLY. LATE is active true when the WD pulse is to be written LATE. If both EARLY and LATE are low when the WD pulse is present, the WD pulse is to be written at nominal. Since write precompensation values vary from disk manufacturer to disk manufacturer, the actual value is determined by several one shots or delay lines which are located external to the FD179X. The write precompensation signals EARLY and LATE are valid for the duration of WD in both FM and MFM formats.

READY

Whenever a Read or Write command (Type II or III) is received the FD179X samples the Ready input. If this input is logic low the command is not executed and an interrupt is generated. All Type I commands are performed regardless of the state of the Ready input. Also, whenever a Type II or III command is received, the TG43 signal output is updated.

COMMAND DESCRIPTION

The FD179X will accept eleven commands. Command words should only be loaded in the Command Register when the Busy status bit is off (Status bit 0). The one exception is the Force Interrupt command. Whenever a command is being executed, the Busy status bit is set. When a command is completed, an interrupt is generated and the Busy status bit is reset. The Status Register indicates whether the completed command encountered an error or was fault free. For ease of discussion, commands are divided into four types. Commands and types are summarized in Table 1.

TABLE 1. COMMAND SUMMARY

A. Commands for Models: 1791, 1792, 1793, 1794

B. Commands for Models: 1795, 1797

Type	Command	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
I	Restore	0	0	0	0	h	V	r1	r0	0	0	0	0	h	V	r1	r0

*NOTE: See Type IV Command Description for further information.

TYPE I COMMANDS

The Type I Commands include the Restore, Seek, Step, Step-In, and Step-Out commands. Each of the Type I Commands contains a rate field (r_0 r_1), which determines the stepping motor rate as defined in Table 3.

A 2 μ s (MFM) or 4 μ s (FM) pulse is provided as an output to the drive. For every step pulse issued, the drive moves one track location in a direction determined by the direction output. The chip will step the drive in the same direction it last stepped unless the command changes the direction.

The Direction signal is active high when stepping in and low when stepping out. The Direction signal is valid 12 μ s before the first stepping pulse is generated.

The rates (shown in Table 3) can be applied to a Step-Direction Motor through the device interface.

TABLE 3. STEPPING RATES

CLK	2 MHz	2 MHz	1 MHz	1 MHz	2 MHz	1 MHz
DDEN	0	1	0	1	x	x
R1 R0	$\overline{\text{TEST}}=1$	$\overline{\text{TEST}}=1$	$\overline{\text{TEST}}=1$	$\overline{\text{TEST}}=1$	$\overline{\text{TEST}}=0$	$\overline{\text{TEST}}=0$
0 0	3 ms	3 ms	6 ms	6 ms	184 μ s	368 μ s
0 1	6 ms	6 ms	12 ms	12 ms	190 μ s	380 μ s
1 0	10 ms	10 ms	20 ms	20 ms	198 μ s	396 μ s
1 1	15 ms	15 ms	30 ms	30 ms	208 μ s	416 μ s

After the last directional step an additional 15 milliseconds of head settling time takes place if the Verify flag is set in Type I commands. Note that this time doubles to 30 ms for a 1 MHz clock. If $\overline{\text{TEST}} = 0$, there is zero settling time. There is also a 15 ms head settling time if the E flag is set in any Type II or III command.

When a Seek, Step or Restore command is executed an optional verification of Read-Write head position can be performed by settling bit 2 ($V = 1$) in the command word to a logic 1. The verification operation begins at the end of the 15 millisecond settling time after the head is loaded against the media. The track number from the first encountered ID Field is compared against the contents of the Track Register. If the track numbers compare and the ID Field Cyclic Redundancy Check (CRC) is correct, the verify operation is complete and an INTRQ is generated with no errors. If there is a match but not a valid CRC, the CRC error status bit is set (Status bit 3), and the next encountered ID field is read from the disk for the verification operation.

★ The FD179X must find an ID field with correct track number and correct CRC within 5 revolutions of the media; otherwise the seek error is set and an INTRQ is generated. If $V = 0$, no verification is performed.

The Head Load (HLD) output controls the movement of the read/write head against the media. HLD is activated at the beginning of a Type I command if the h flag is set ($h = 1$), at the end of the Type I command if the verify flag ($V = 1$), or upon receipt of any Type II or III command. Once HLD is active it remains active until either a Type I command is received with ($h = 0$ and $V = 0$); or if the FD179X is in an idle state (non-busy) and 15 index pulses have occurred.

Head Load timing (HLT) is an input to the FD179X which is used for the head engage time. When $\text{HLT} = 1$, the FD179X assumes the head is completely engaged. The head engage time is typically 30 to 100 ms depending on drive. The low to high transition on HLD is typically used to fire a one shot. The output of the one shot is then used for HLT and supplied as an input to the FD179X.

HEAD LOAD TIMING

When both HLD and HLT are true, the FD179X will then read from or write to the media. The "and" of HLD and HLT appears as status Bit 5 in Type I status.

In summary for the Type I commands: if $h = 0$ and $V = 0$, HLD is reset. If $h = 1$ and $V = 0$, HLD is set at the beginning of the command and HLT is not sampled nor is there an internal 15 ms delay. If $h = 0$ and $V = 1$, HLD is set near the end of the command, an internal 15 ms occurs, and the FD179X waits for HLT to be true. If $h = 1$ and $V = 1$, HLD is set at the beginning of the command. Near the end of the command, after all the steps have been issued, an internal 15 ms delay occurs and the FD179X then waits for HLT to occur.

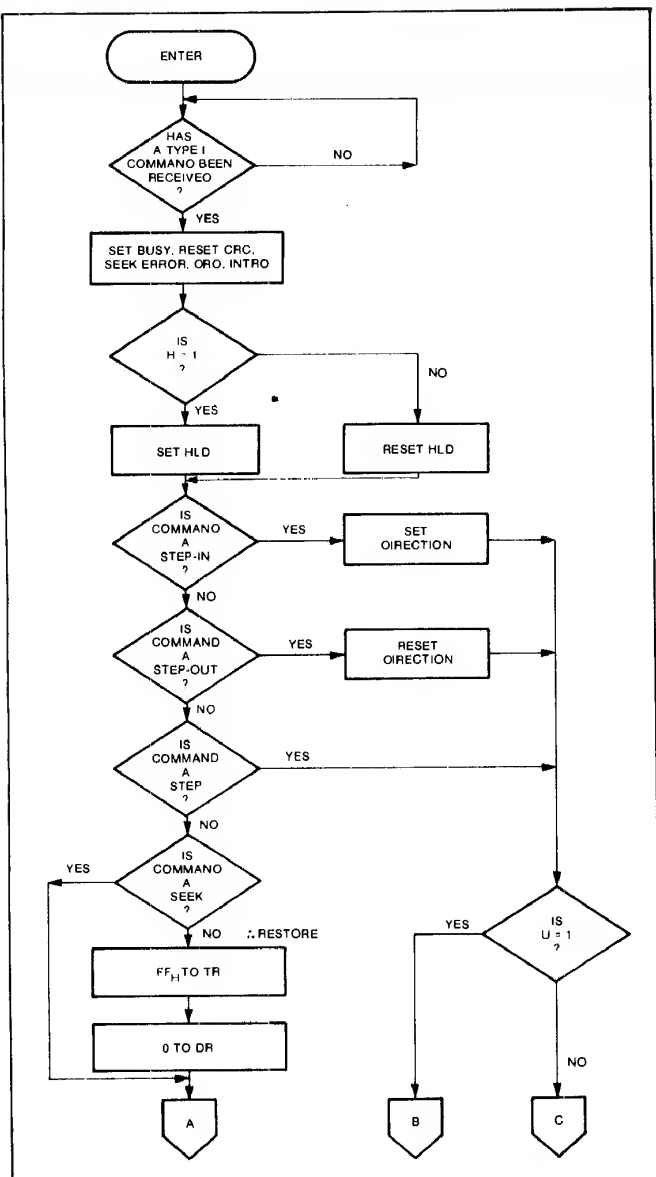

For Type II and III commands with E flag off, HLD is made active and HLT is sampled until true. With E flag on, HLD is made active, an internal 15 ms delay occurs and then HLT is sampled until true.

RESTORE (SEEK TRACK 0)

Upon receipt of this command the Track 00 ($\overline{\text{TR00}}$) input is sampled. If $\overline{\text{TR00}}$ is active low indicating the Read-Write head is positioned over track 0, the Track Register is loaded with zeroes and an interrupt is generated. If $\overline{\text{TR00}}$ is not active low, stepping pulses (pins 15 to 16) at a rate specified by the r_1 r_0 field are issued until the $\overline{\text{TR00}}$ input is activated. At this time the Track Register is loaded with zeroes and an interrupt is generated. If the $\overline{\text{TR00}}$ input does not go active low after 255 stepping pulses, the FD179X terminates operation, interrupts, and sets the Seek error status bit, providing the V flag is set. A verification operation also takes place if the V flag is set. The h bit allows the head to be loaded at the start of command. Note that the Restore command is executed when $\overline{\text{MR}}$ goes from an active to an inactive state and that the DRQ pin stays low.

SEEK

This command assumes that the Track Register contains the track number of the current position of the Read-Write head and the Data Register contains the desired track number. The FD179X will update the Track register and issue stepping pulses in the appropriate direction until the contents of the Track register are equal to the contents of

TYPE I COMMAND FLOW

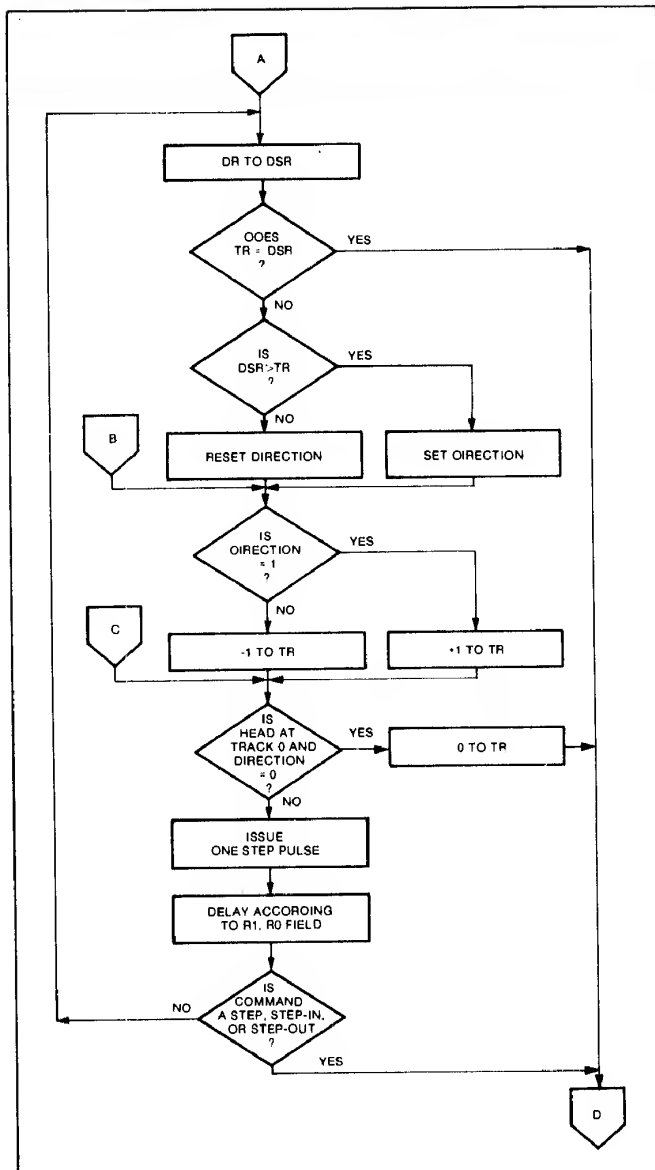

the Data Register (the desired track location). A verification operation takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command. Note: When using multiple drives, the track register must be updated for the drive selected before seeks are issued.

STEP

Upon receipt of this command, the FD179X issues one stepping pulse to the disk drive. The stepping motor direction is the same as in the previous step command. After a delay determined by the $r1r0$ field, a verification takes place if the V flag is on. If the U flag is on, the Track Register is updated. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP-IN

Upon receipt of this command, the FD179X issues one stepping pulse in the direction towards track 76. If the U

TYPE I COMMAND FLOW

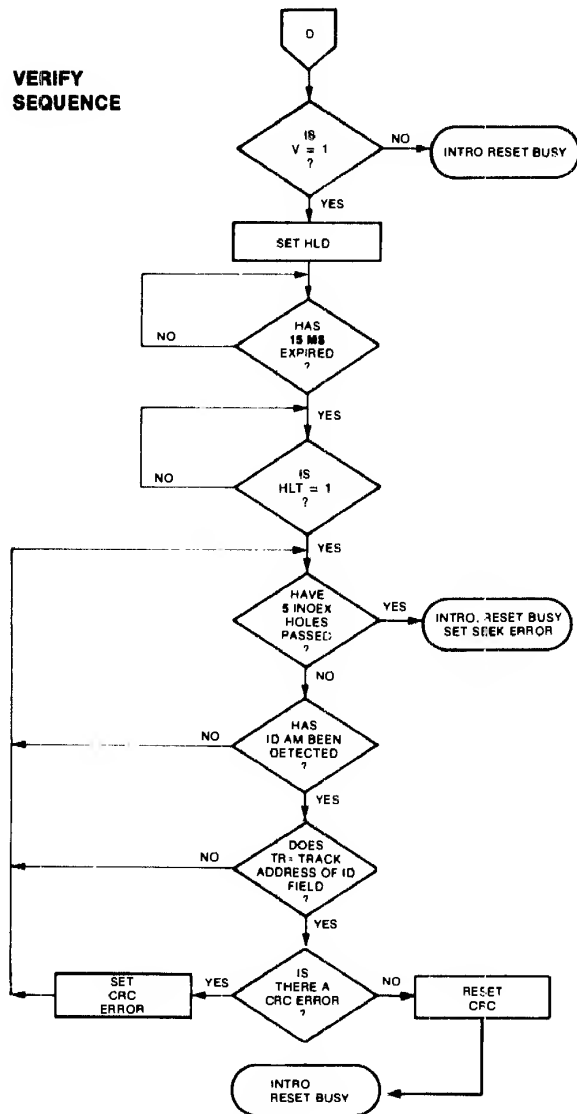

flag is on, the Track Register is incremented by one. After a delay determined by the $r1r0$ field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP-OUT

Upon receipt of this command, the FD179X issues one stepping pulse in the direction towards track 0. If the U flag is on, the Track Register is decremented by one. After a delay determined by the $r1r0$ field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

EXCEPTIONS

On the 1795/7 devices, the SSO output is not affected during Type 1 commands, and an internal side compare does not take place when the (V) Verify Flag is on.

VERIFY
SEQUENCE

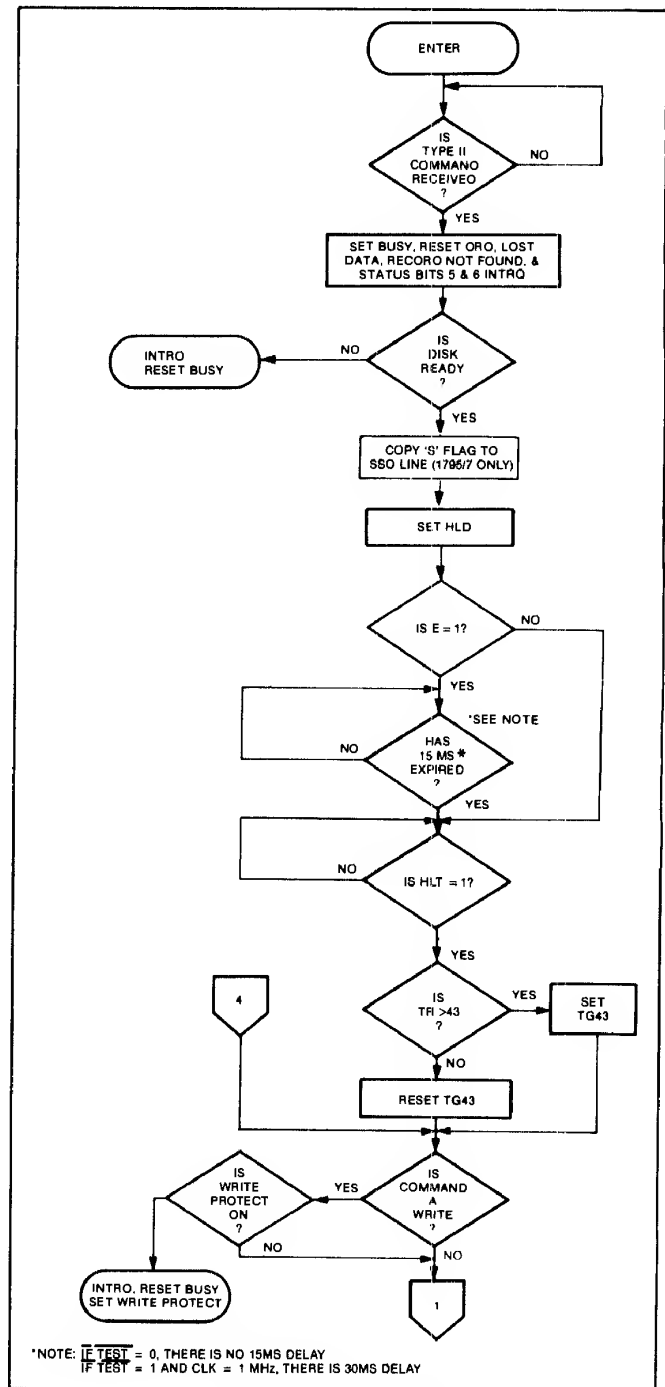

TYPE I COMMAND FLOW

TYPE II COMMANDS

The Type II Commands are the Read Sector and Write Sector commands. Prior to loading the Type II Command into the Command Register, the computer must load the Sector Register with the desired sector number. Upon receipt of the Type II command, the busy status Bit is set. If the E flag = 1 (this is the normal case) HLD is made active and HLT is sampled after a 15 msec delay. If the E flag is 0, the head is loaded and HLT sampled with no 15 msec delay. The ID field and Data Field format are shown on page 13.

When an ID field is located on the disk, the FD179X compares the Track Number on the ID field with the Track Register. If there is not a match, the next encountered ID field is read and a comparison is again made. If there was a match, the Sector Number of the ID field is compared with the Sector Register. If there is not a Sector match, the next encountered ID field is read off the disk and comparisons again made. If the ID field CRC is correct, the data field is

then located and will be either written into, or read from depending upon the command. The FD179X must find an ID field with a Track number, Sector number, side number, and CRC within four revolutions of the disk; otherwise, the Record not found status bit is set (Status bit 3) and the command is terminated with an interrupt.

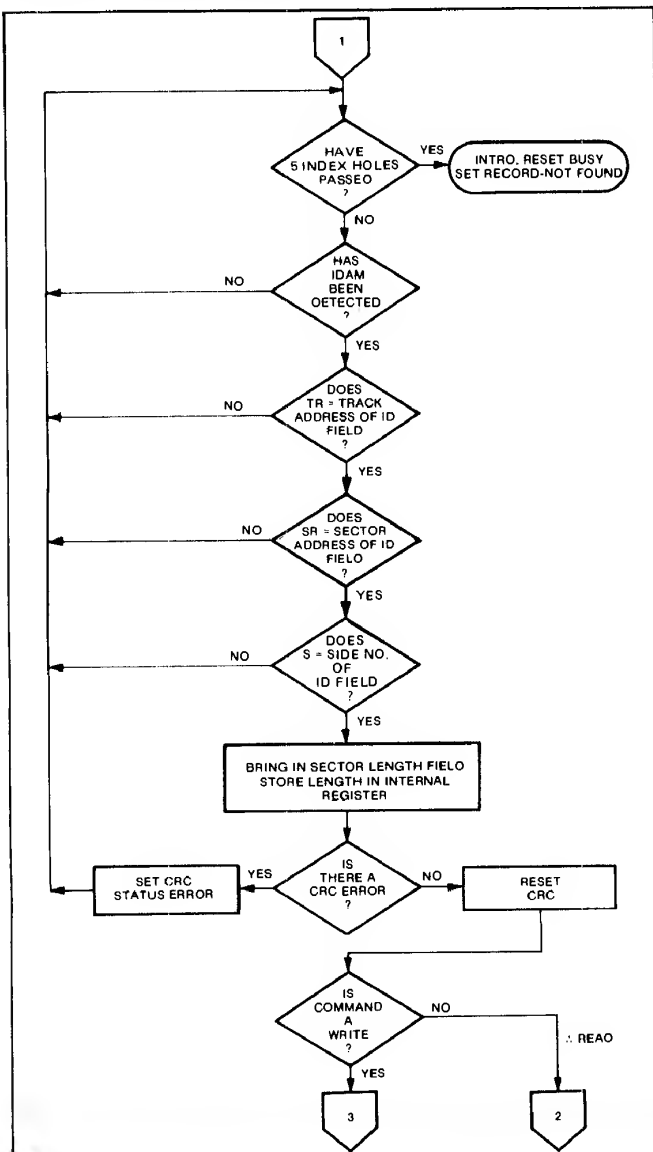

TYPE II COMMAND

Each of the Type II Commands contains an (m) flag which determines if multiple records (sectors) are to be read or written, depending upon the command. If m = 0, a single sector is read or written and an interrupt is generated at the completion of the command. If m = 1, multiple records are read or written with the sector register internally updated so that an address verification can occur on the next

record. The FD179X will continue to read or write multiple records and update the sector register in numerical ascending sequence until the sector register exceeds the number of sectors on the track or until the Force Interrupt command is loaded into the Command Register, which terminates the command and generates an interrupt.

For example: If the FD179X is instructed to read sector 27 and there are only 26 on the track, the sector register exceeds the number available. The FD179X will search for 5 disk revolutions, interrupt out, reset busy, and set the record not found status bit.

The Type II commands for 1791-94 also contain side select compare flags. When C = 0 (Bit 1) no side comparison is made. When C = 1, the LSB of the side number is read off the ID Field of the disk and compared with the contents of the (S) flag (Bit 3). If the S flag compares with the side number recorded in the ID field, the FD179X continues with the ID search. If a comparison is not made within 5 index pulses, the interrupt line is made active and the Record-Not-Found status bit is set.

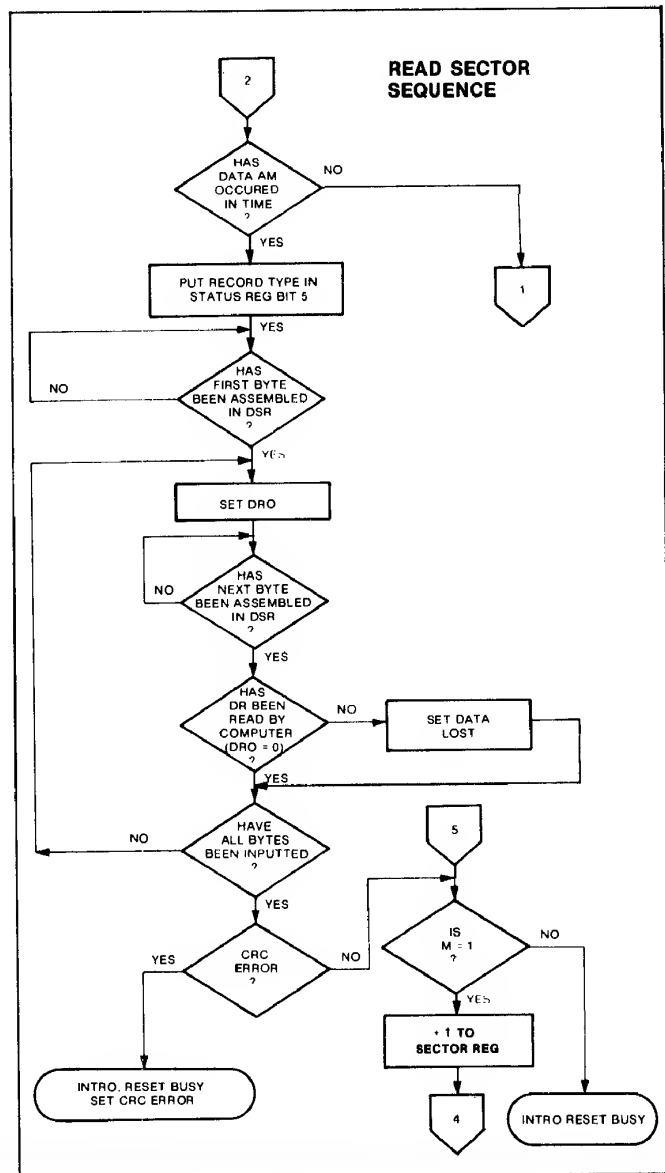

TYPE II COMMAND

The Type II and III commands for the 1795-97 contain a side select flag (Bit 1). When U = 0, SSO is updated to 0. Similarly, U = 1 updates SSO to 1. The chip compares the SSO to the ID field. If they do not compare within 5 revolutions the interrupt line is made active and the RNF status bit is set.

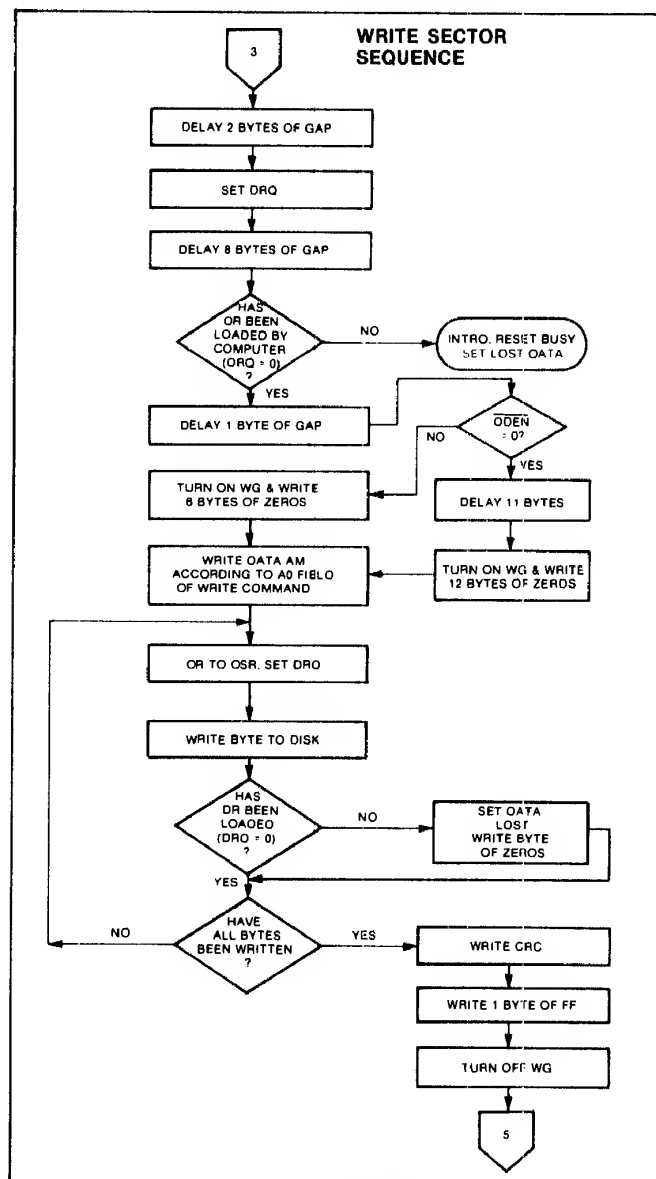

The 1795/7 READ SECTOR and WRITE SECTOR commands include a 'L' flag. The 'L' flag, in conjunction with the sector length byte of the ID Field, allows different byte lengths to be implemented in each sector. For IBM compatibility, the 'L' flag should be set to a one.

READ SECTOR

Upon receipt of the Read Sector command, the head is loaded, the Busy status bit set, and when an ID field is encountered that has the correct track number, correct sector number, correct side number, and correct CRC, the data field is presented to the computer. The Data Address

TYPE II COMMAND

TYPE II COMMAND

Mark of the data field must be found within 30 bytes in single density and 43 bytes in double density of the last ID field CRC byte; if not, the ID field is searched for and verified again followed by the Data Address Mark search. If after 5 revolutions the DAM cannot be found, the Record Not Found status bit is set and the operation is terminated. When the first character or byte of the data field has been shifted through the DSR, it is transferred to the DR, and DRQ is generated. When the next byte is accumulated in the DSR, it is transferred to the DR and another DRQ is generated. If the Computer has not read the previous contents of the DR before a new character is transferred that character is lost and the Lost Data Status bit is set. This sequence continues until the complete data field has been inputted to the computer. If there is a CRC error at the end of the data field, the CRC error status bit is set, and the command is terminated (even if it is a multiple record command).

At the end of the Read operation, the type of Data Address Mark encountered in the data field is recorded in the Status Register (Bit 5) as shown:

STATUS BIT 5

1	Deleted Data Mark
0	Data Mark

WRITE SECTOR

Upon receipt of the Write Sector command, the head is loaded (HLD active) and the Busy status bit is set. When an ID field is encountered that has the correct track number, correct sector number, correct side number, and correct CRC, a DRQ is generated. The FD179X counts off 11 bytes in single density and 22 bytes in double density from the CRC field and the Write Gate (WG) output is made active if the DRQ is serviced (i.e., the DR has been loaded by the computer). If DRQ has not been serviced, the command is terminated and the Lost Data status bit is set. If the DRQ has been serviced, the WG is made active and six bytes of zeroes in single density and 12 bytes in double density are then written on the disk. At this time the Data Address Mark is then written on the disk as determined by the *a0* field of the command as shown below:

a0 Data Address Mark (Bit 0)

1	Deleted Data Mark
0	Data Mark

The FD179X then writes the data field and generates DRQ's to the computer. If the DRQ is not serviced in time for continuous writing the Lost Data Status Bit is set and a byte of zeroes is written on the disk. The command is not terminated. After the last data byte has been written on the disk, the two-byte CRC is computed internally and written on the disk followed by one byte of logic ones in FM or in MFM. The WG output is then deactivated. For a 2 MHz clock the INTRQ will set 8 to 12 μ sec after the last CRC byte is written. For partial sector writing, the proper method is to write the data and fill the balance with zeroes. By letting the chip fill the zeroes, errors may be masked by the lost data status and improper CRC Bytes.

TYPE III COMMANDS

READ ADDRESS

Upon receipt of the Read Address command, the head is loaded and the Busy Status Bit is set. The next encountered ID field is then read in from the disk, and the six data bytes of the ID field are assembled and transferred to the DR, and a DRQ is generated for each byte. The six bytes of the ID field are shown below:

TRACK ADDR	SIDE NUMBER	SECTOR ADDRESS	SECTOR LENGTH	CRC 1	CRC 2
1	2	3	4	5	6

Although the CRC characters are transferred to the computer, the FD179X checks for validity and the CRC error status bit is set if there is a CRC error. The Track Address of the ID field is written into the sector register so that a comparison can be made by the user. At the end of the operation an interrupt is generated and the Busy Status is reset.

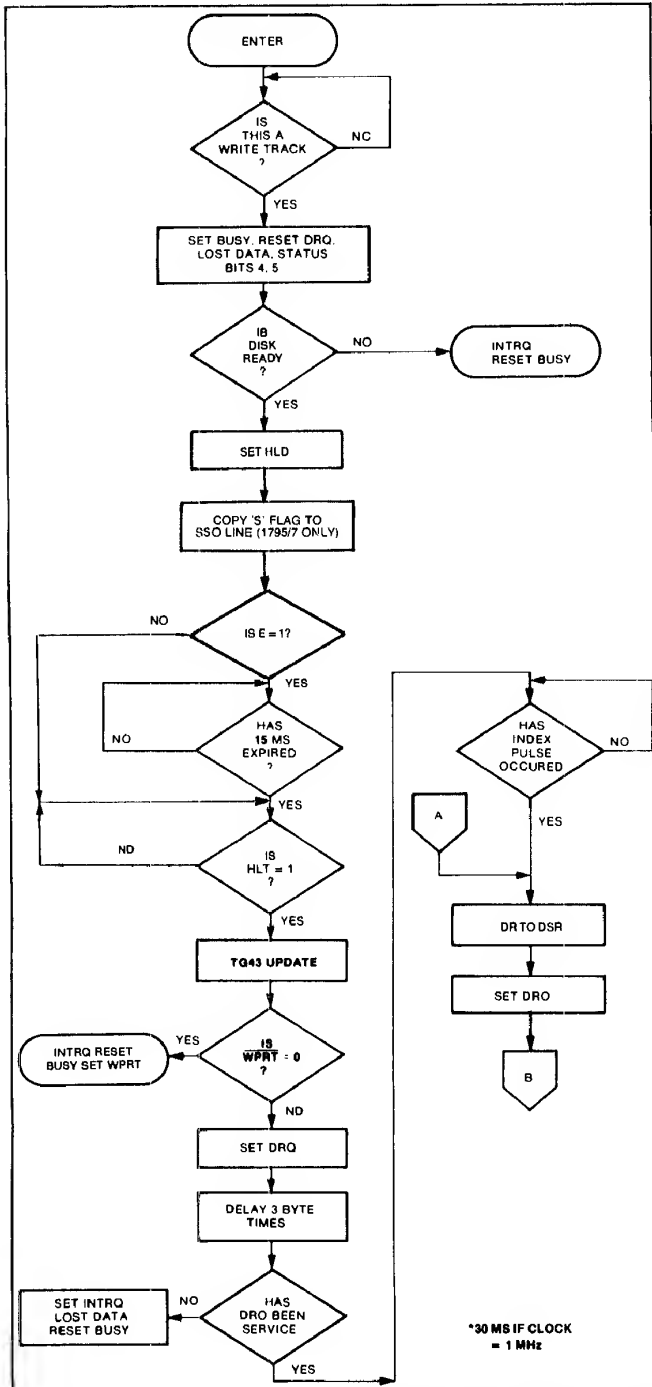

READ TRACK

Upon receipt of the READ track command, the head is loaded, and the Busy Status bit is set. Reading starts with the leading edge of the first encountered index pulse and continues until the next index pulse. All Gap, Header, and data bytes are assembled and transferred to the data register and DRQ's are generated for each byte. The accumulation of bytes is synchronized to each address mark encountered. An interrupt is generated at the completion of the command.

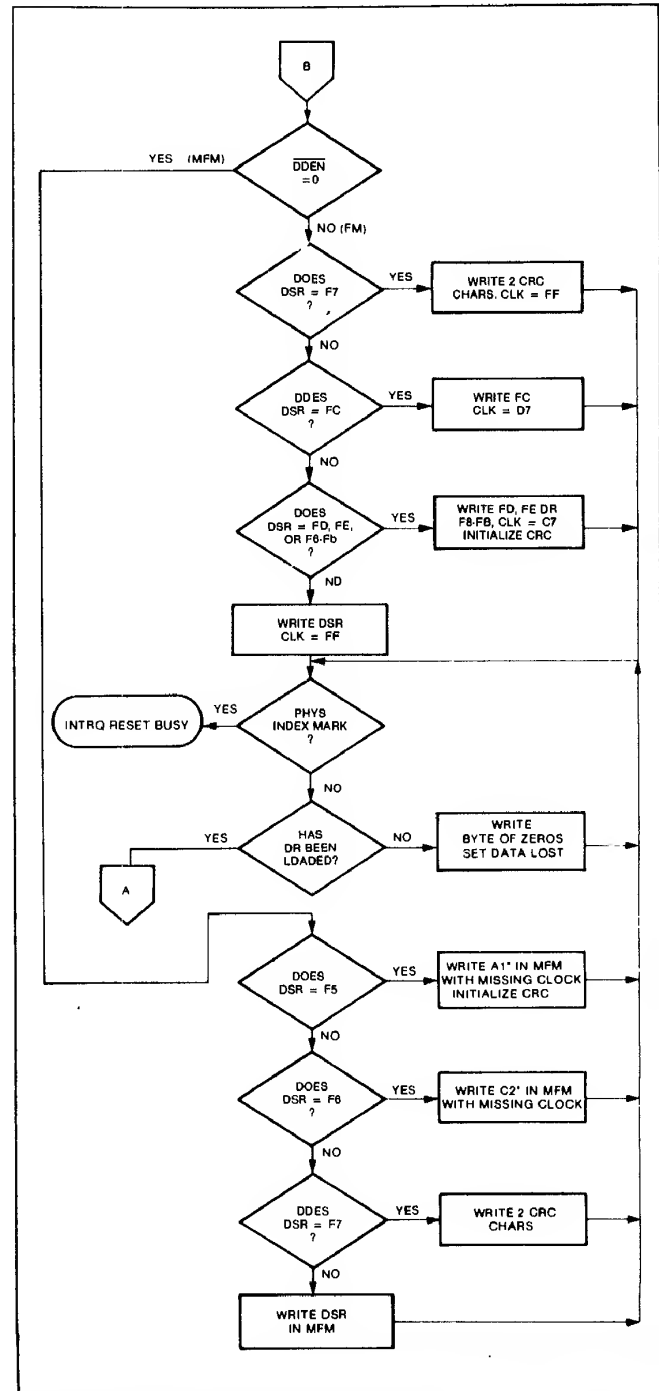

This command has several characteristics which make it suitable for diagnostic purposes. They are: the Read Gate

is not activated during the command; no CRC checking is performed; gap information is included in the data stream; the internal side compare is not performed; and the address mark detector is on for the duration of the command. Because the A.M. detector is always on, write splices or noise may cause the chip to look for an A.M. If an address mark does not appear on schedule the Lost Data status flag is set.

The ID A.M., ID field, ID CRC bytes, DAM, Data, and Data CRC Bytes for each sector will be correct. The Gap Bytes may be read incorrectly during write-splice time because of synchronization.

TYPE III COMMAND WRITE TRACK

CONTROL BYTES FOR INITIALIZATION

DATA PATTERN IN DR (HEX)	FD179X INTERPRETATION IN FM ($\overline{DDEN} = 1$)	FD1791/3 INTERPRETATION IN MFM ($\overline{DDEN} = 0$)
00 thru F4	Write 00 thru F4 with CLK = FF	Write 00 thru F4, in MFM
F5	Not Allowed	Write A1* in MFM, Preset CRC
F6	Not Allowed	Write C2** in MFM
F7	Generate 2 CRC bytes	Generate 2 CRC bytes
F8 thru FB	Write F8 thru FB, Clk = C7, Preset CRC	Write F8 thru FB, in MFM
FC	Write FC with Clk = D7	Write FC in MFM
FD	Write FD with Clk = FF	Write FD in MFM
FE	Write FE, Clk = C7, Preset CRC	Write FE in MFM
FF	Write FF with Clk = FF	Write FF in MFM

*Missing clock transition between bits 4 and 5

**Missing clock transition between bits 3 & 4

WRITE TRACK FORMATTING THE DISK

(Refer to section on Type III commands for flow diagrams.)

Formatting the disk is a relatively simple task when operating programmed I/O or when operating under DMA with a large amount of memory. Data and gap information must be provided at the computer interface. Formatting the disk is accomplished by positioning the R/W head over the desired track number and issuing the Write Track command.

Upon receipt of the Write Track command, the head is loaded and the Busy Status bit is set. Writing starts with the leading edge of the first encountered index pulse and continues until the next index pulse, at which time the interrupt is activated. The Data Request is activated immediately upon receiving the command, but writing will not start until after the first byte has been loaded into the Data Register. If the DR has not been loaded by the time the index pulse is encountered the operation is terminated making the device Not Busy, the Lost Data Status Bit is set, and the Interrupt is activated. If a byte is not present in the DR when needed, a byte of zeroes is substituted.

This sequence continues from one index mark to the next index mark. Normally, whatever data pattern appears in the data register is written on the disk with a normal clock pattern. However, if the FD179X detects a data pattern of F5 thru FE in the data register, this is interpreted as data address marks with missing clocks or CRC generation.

The CRC generator is initialized when any data byte from F8 to FE is about to be transferred from the DR to the DSR in FM or by receipt of F5 in MFM. An F7 pattern will generate two CRC characters in FM or MFM. As a consequence, the patterns F5 thru FE must not appear in the gaps, data fields, or ID fields. Also, CRC's must be generated by an F7 pattern.

Disks may be formatted in IBM 3740 or System 34 formats with sector lengths of 128, 256, 512, or 1024 bytes.

TYPE IV COMMANDS

The Forced Interrupt command is generally used to terminate a multiple sector read or write command or to in-

sure Type I status in the status register. This command can be loaded into the command register at any time. If there is a current command under execution (busy status bit set) the command will be terminated and the busy status bit reset.

The lower four bits of the command determine the conditional interrupt as follows:

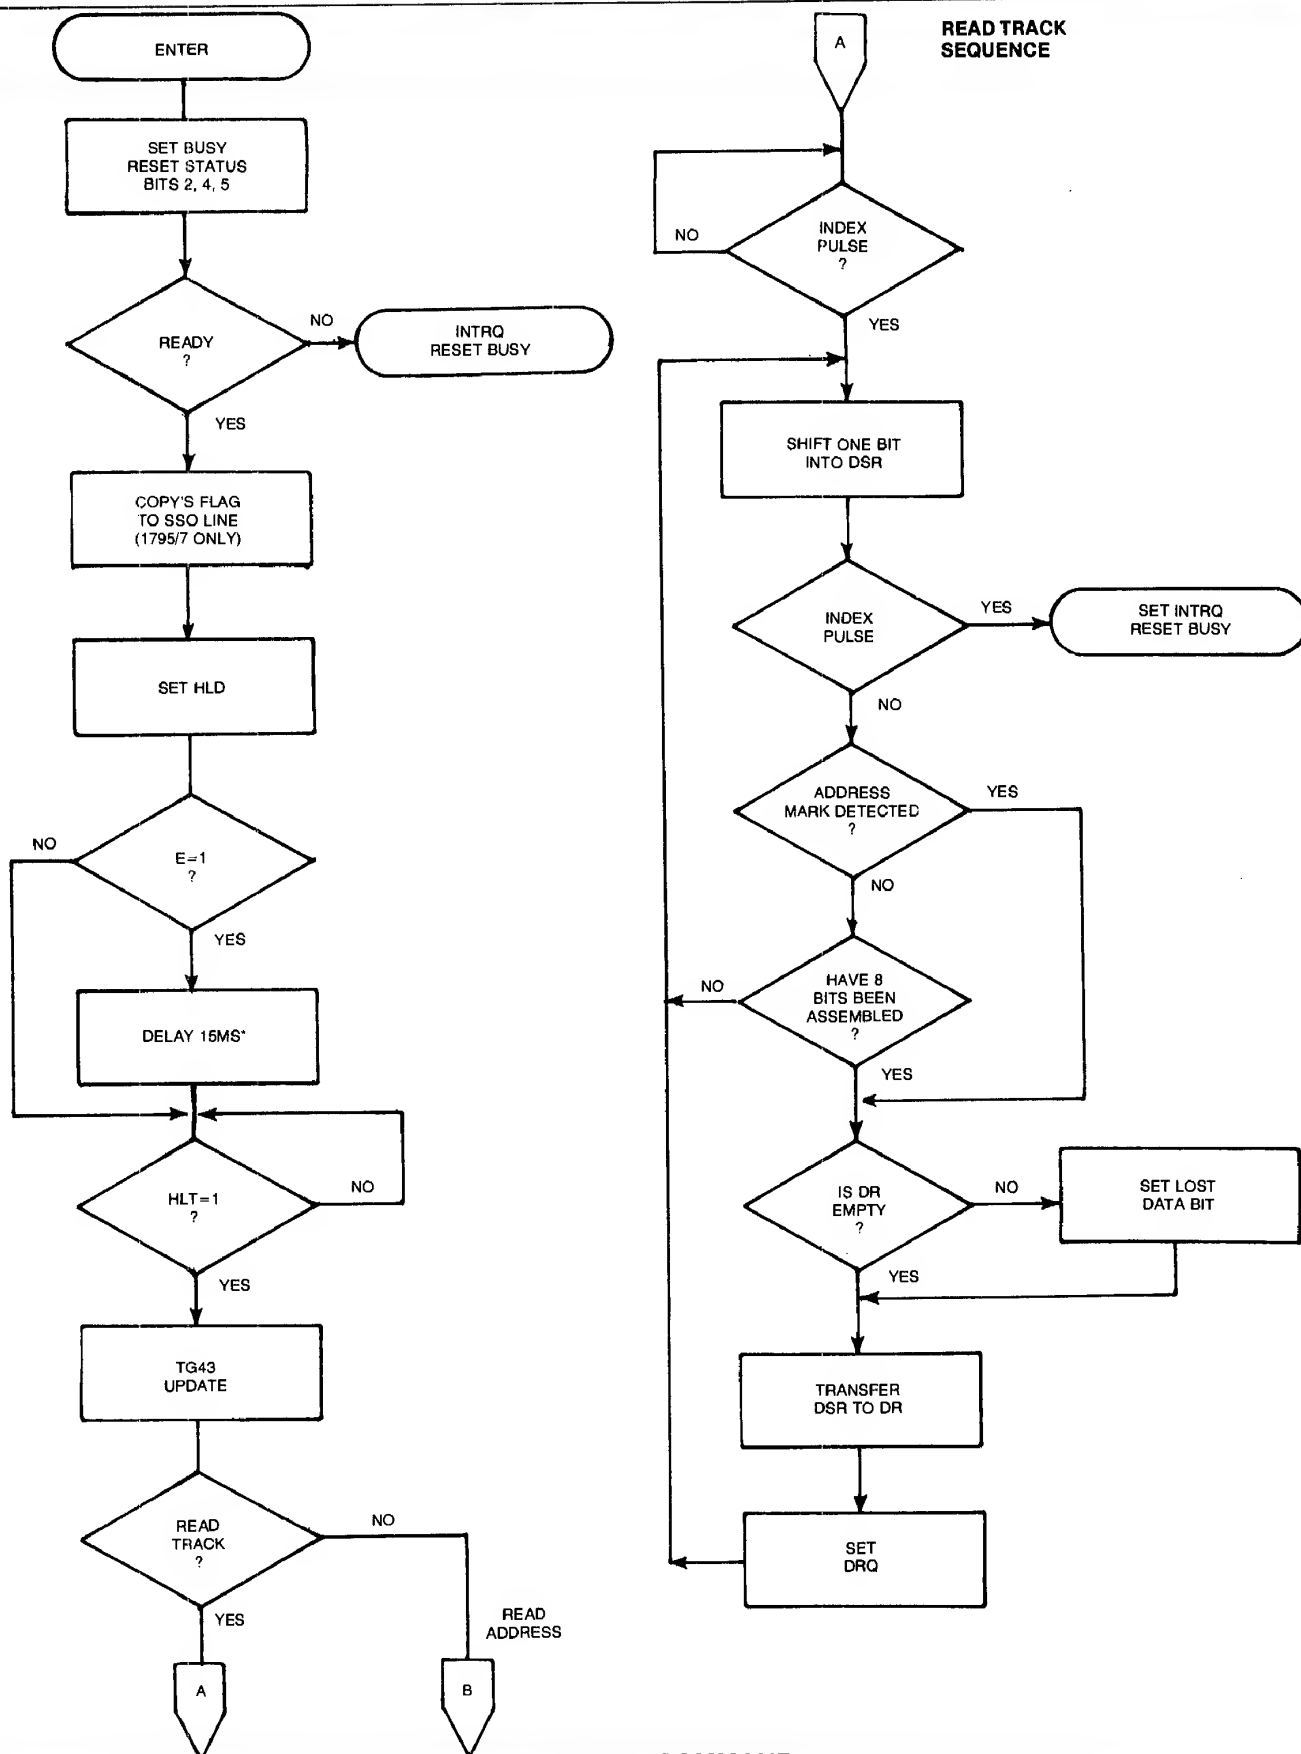

- I₀ = Not-Ready to Ready Transition
- I₁ = Ready to Not-Ready Transition
- I₂ = Every Index Pulse
- I₃ = Immediate Interrupt

The conditional interrupt is enabled when the corresponding bit positions of the command (I₃ - I₀) are set to a 1. Then, when the condition for interrupt is met, the INTRQ line will go high signifying that the condition specified has occurred. If I₃ - I₀ are all set to zero (HEX D0), no interrupt will occur but any command presently under execution will be immediately terminated. When using the immediate interrupt condition (I₃ = 1) an interrupt will be immediately generated and the current command terminated. Reading the status or writing to the command register will not automatically clear the interrupt. The HEX D0 is the only command that will enable the immediate interrupt (HEX D8) to clear on a subsequent load command register or read status register operation. Follow a HEX D8 with D0 command.

Wait 8 micro sec (double density) or 16 micro sec (single density) before issuing a new command after issuing a forced interrupt (times double when clock = 1 MHz). Loading a new command sooner than this will nullify the forced interrupt.

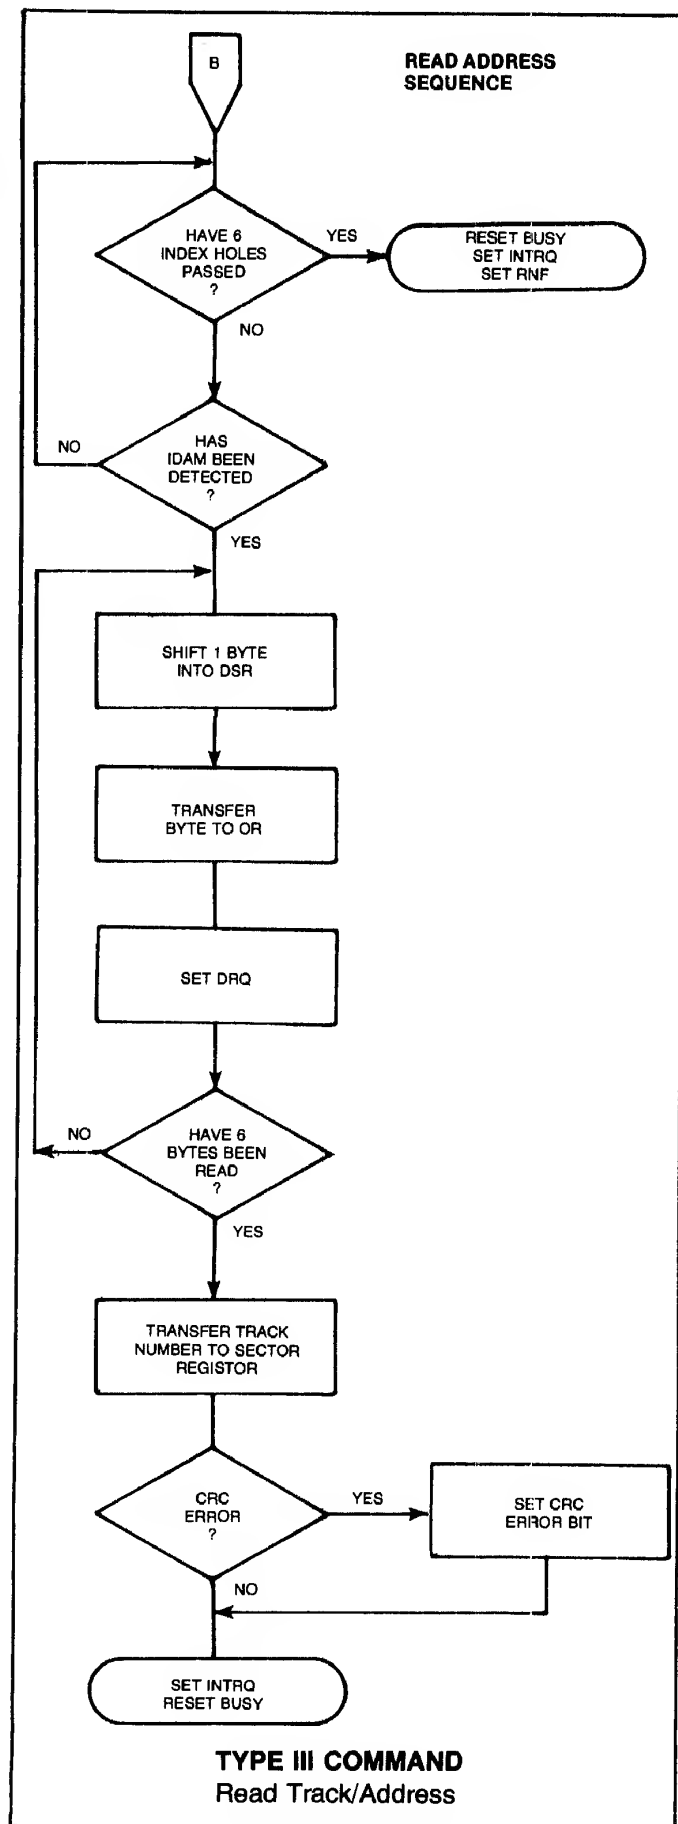

Forced interrupt stops any command at the end of an internal micro-instruction and generates INTRQ when the specified condition is met. Forced interrupt will wait until ALU operations in progress are complete (CRC calculations, compares, etc.).

More than one condition may be set at a time. If for example, the READY TO NOT-READY condition (I₁ = 1) and the Every Index Pulse (I₂ = 1) are both set, the resultant command would be HEX "DA". The "OR" function is performed so that either a READY TO NOT-READY or the next Index Pulse will cause an interrupt condition.

*If TEST = ϕ , NO DELAY
If TEST = 1 and CLK = 1 MHZ, 30 MS DELAY

TYPE III COMMAND
Read Track/Address

STATUS REGISTER

Upon receipt of any command, except the Force Interrupt command, the Busy Status bit is set and the rest of the status bits are updated or cleared for the new command. If the Force Interrupt Command is received when there is a current command under execution, the Busy status bit is reset, and the rest of the status bits are unchanged. If the Force Interrupt command is received when there is not a current command under execution, the Busy Status bit is reset and the rest of the status bits are updated or cleared. In this case, Status reflects the Type I commands.

The user has the option of reading the status register through program control or using the DRQ line with DMA or interrupt methods. When the Data register is read the DRQ bit in the status register and the DRQ line are automatically reset. A write to the Data register also causes both DRQ's to reset.

The busy bit in the status may be monitored with a user program to determine when a command is complete, in lieu of using the INTRQ line. When using the INTRQ, a busy status check is not recommended because a read of the status register to determine the condition of busy will reset the INTRQ line.

The format of the Status Register is shown below:

(BITS)							
7	6	5	4	3	2	1	0
S7	S6	S5	S4	S3	S2	S1	S0

Status varies according to the type of command executed as shown in Table 4.

Because of internal sync cycles, certain time delays must be observed when operating under programmed I/O. They are: (times double when clock = 1 MHz)

Operation	Next Operation	Delay Req'd.	
		FM	MFM
Write to Command Reg.	Read Busy Bit (Status Bit 0)	12 μ s	6 μ s
Write to Command Reg.	Read Status Bits 1-7	28 μ s	14 μ s
Write Any Register	Read From Diff. Register	0	0

IBM 3740 FORMAT — 128 BYTES/SECTOR

Shown below is the IBM single-density format with 128 bytes/sector. In order to format a diskette, the user must issue the Write Track command, and load the data register with the following values. For every byte to be written, there is one Data Request.

IBM 3740 FORMAT — 128 BYTES/SECTOR

Shown below is the IBM single-density format with 128 bytes/sector. In order to format a diskette, the user must issue the Write Track command, and load the data register with the following values. For every byte to be written, there is one Data Request.

NUMBER OF BYTES	HEX VALUE OF BYTE WRITTEN
40	FF (or 00)*
6	00
1	FC (Index Mark)
* 26	FF (or 00)*
6	00
1	FE (ID Address Mark)
1	Track Number
1	Side Number (00 or 01)
1	Sector Number (1 thru 1A)
1	00 (Sector Length)
1	F7 (2 CRC's written)
11	FF (or 00)*
6	00
1	FB (Data Address Mark)
128	Data (IBM uses E5)
1	F7 (2 CRC's written)
27	FF (or 00)*
247**	FF (or 00)*

*Write bracketed field 26 times

**Continue writing until FD179X interrupts out.

Approx. 247 bytes.

1-Optional '00' on 1795/7 only.

IBM SYSTEM 34 FORMAT- 256 BYTES/SECTOR

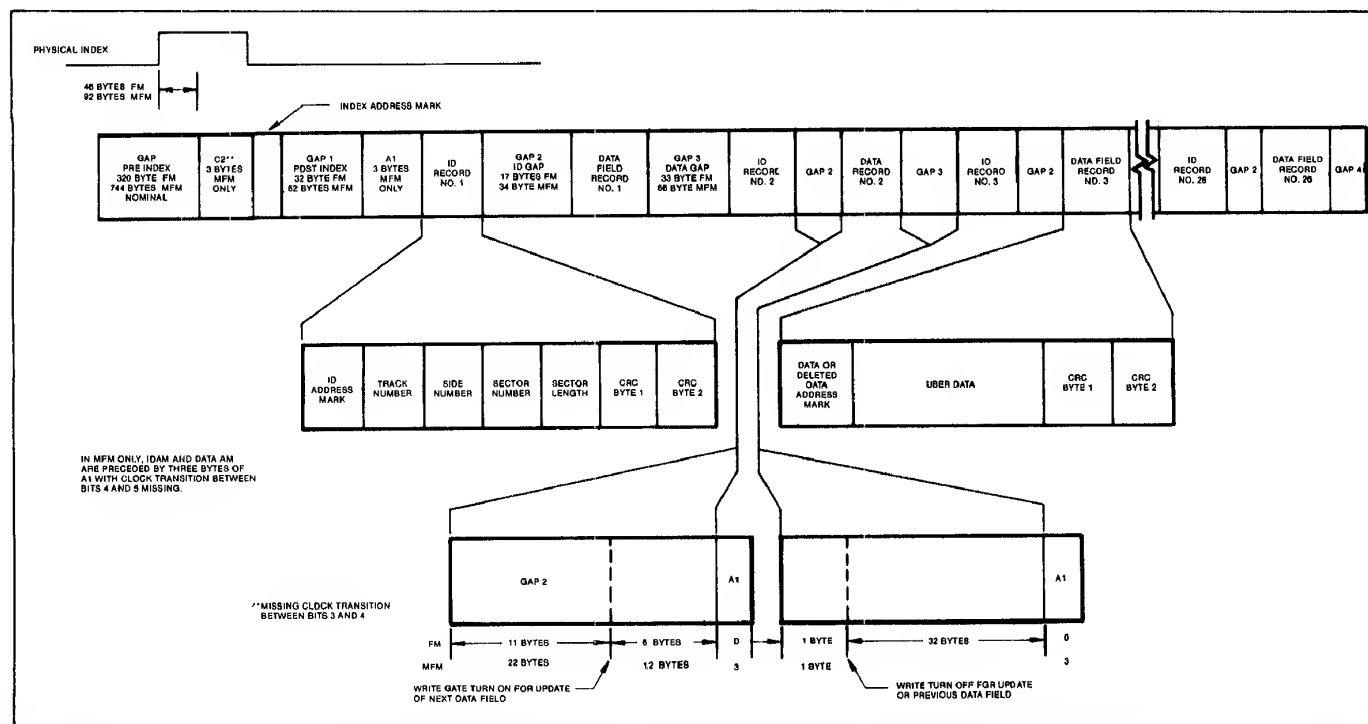

Shown below is the IBM dual-density format with 256 bytes/sector. In order to format a diskette the user must issue the Write Track command and load the data register with the following values. For every byte to be written, there is one data request.

NUMBER OF BYTES	HEX VALUE OF BYTE WRITTEN
80	4E
12	00
3	F6 (Writes C2)
1	FC (Index Mark)
* 50	4E
12	00
3	F5 (Writes A1)
1	FE (ID Address Mark)
1	Track Number (0 thru 4C)
1	Side Number (0 or 1)
1	Sector Number (1 thru 1A)
1	01 (Sector Length)
1	F7 (2 CRCs written)
22	4E
12	00
3	F5 (Writes A1)
1	FB (Data Address Mark)
256	DATA
1	F7 (2 CRCs written)
54	4E
598**	4E

*Write bracketed field 26 times

**Continue writing until FD179X interrupts out.

Approx. 598 bytes.

IBM TRACK FORMAT

1. NON-IBM FORMATS

Variations in the IBM formats are possible to a limited extent if the following requirements are met:

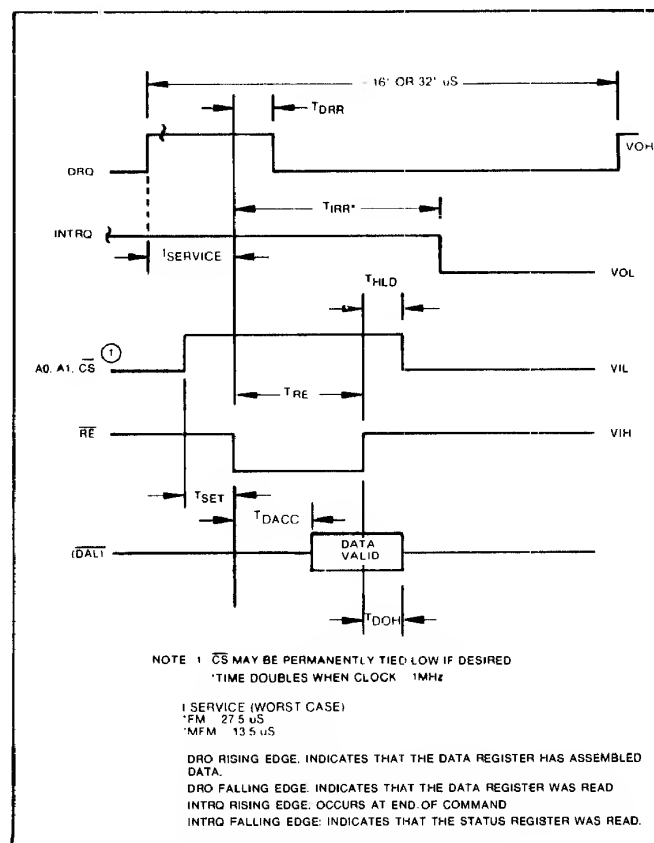

- 1) Sector size must be 128, 256, 512 or 1024 bytes.
- 2) Gap 2 cannot be varied from the IBM format.
- 3) 3 bytes of A1 must be used in MFM.

In addition, the Index Address Mark is not required for operation by the FD179X. Gap 1, 3, and 4 lengths can be as short as 2 bytes for FD179X operation, however PLL lock up time, motor speed variation, write-splice area, etc. will add more bytes to each gap to achieve proper operation. It is recommended that the IBM format be used for highest system reliability.

	FM	MFM
Gap I	16 bytes FF	32 bytes 4E
Gap II	11 bytes FF	22 bytes 4E
*	6 bytes 00	12 bytes 00
*		3 bytes A1
Gap III**	10 bytes FF 4 bytes 00	24 bytes 4E 8 bytes 00 3 bytes A1
Gap IV	16 bytes FF	16 bytes 4E

*Byte counts must be exact.

**Byte counts are minimum, except exactly 3 bytes of A1 must be written.

TIP	Index Pulse Width	10			μsec	
TWF	Write Fault Pulse Width	10			μsec	

MISCELLANEOUS TIMING

*FROM STEP RATE TABLE

NOTES:

1. Pulse width on RAW READ (Pin 27) is normally 100-300 ns. However, pulse may be any width if pulse is entirely within window. If pulse occurs in both windows, then pulse width must be less than 300 ns for MFM at CLK = 2 MHz and 600 ns for FM at 2 MHz. Times double for 1 MHz.
2. A PPL Data Separator is recommended for 8" MFM.
3. tbc should be 2 μ s, nominal in MFM and 4 μ s nominal in FM. Times double when CLK = 1 MHz.
4. RCLK may be high or low during RAW READ (Polarity is unimportant).
5. Times double when clock = 1 MHz.
6. Output timing readings are at $V_{OL} = 0.8v$ and $V_{OH} = 2.0v$.

Table 4. STATUS REGISTER SUMMARY

BIT	ALL TYPE I COMMANDS	READ ADDRESS	READ SECTOR	READ TRACK	WRITE SECTOR	WRITE TRACK
S7	NOT READY	NOT READY	NOT READY	NOT READY	NOT READY	NOT READY
S6	WRITE PROTECT	0	0	0	WRITE PROTECT	WRITE PROTECT
S5	HEAD LOADED	0	RECORD TYPE	0	WRITE FAULT	WRITE FAULT
S4	SEEK ERROR	RNF	RNF	0	RNF	0
S3	CRC ERROR	CRC ERROR	CRC ERROR	0	CRC ERROR	0
S2	TRACK 0	LOST DATA	LOST DATA	LOST DATA	LOST DATA	LOST DATA
S1	INDEX PULSE	DRQ	DRQ	DRQ	DRQ	DRQ
S0	BUSY	BUSY	BUSY	BUSY	BUSY	BUSY

STATUS FOR TYPE I COMMANDS

BIT NAME	MEANING
S7 NOT READY	This bit when set indicates the drive is not ready. When reset it indicates that the drive is ready. This bit is an inverted copy of the Ready input and logically 'ored' with MR.
S6 PROTECTED	When set, indicates Write Protect is activated. This bit is an inverted copy of WRPT input.
S5 HEAD LOADED	When set, it indicates the head is loaded and engaged. This bit is a logical "and" of HLD and HLT signals.
S4 SEEK ERROR	When set, the desired track was not verified. This bit is reset to 0 when updated.
S3 CRC ERROR	CRC encountered in ID field.
S2 TRACK 00	When set, indicates Read/Write head is positioned to Track 0. This bit is an inverted copy of the TROO input.
S1 INDEX	When set, indicates index mark detected from drive. This bit is an inverted copy of the IP input.
S0 BUSY	When set command is in progress. When reset no command is in progress.

STATUS FOR TYPE II AND III COMMANDS

BIT NAME	MEANING
S7 NOT READY	This bit when set indicates the drive is not ready. When reset, it indicates that the drive is ready. This bit is an inverted copy of the Ready input and 'ored' with MR. The Type II and III Commands will not execute unless the drive is ready.
S6 WRITE PROTECT	On Read Record: Not Used. On Read Track: Not Used. On any Write: It indicates a Write Protect. This bit is reset when updated.
S5 RECORD TYPE/ WRITE FAULT	On Read Record: It indicates the record-type code from data field address mark. 1 = Deleted Data Mark. 0 = Data Mark. On any Write: It indicates a Write Fault. This bit is reset when updated.
S4 RECORD NOT FOUND (RNF)	When set, it indicates that the desired track, sector, or side were not found. This bit is reset when updated.
S3 CRC ERROR	If S4 is set, an error is found in one or more ID fields; otherwise it indicates error in data field. This bit is reset when updated.
S2 LOST DATA	When set, it indicates the computer did not respond to DRQ in one byte time. This bit is reset to zero when updated.
S1 DATA REQUEST	This bit is a copy of the DRQ output. When set, it indicates the DR is full on a Read Operation or the DR is empty on a Write operation. This bit is reset to zero when updated.
S0 BUSY	When set, command is under execution. When reset, no command is under execution.

ELECTRICAL CHARACTERISTICS**Absolute Maximum Ratings**

V_{DD} with respect to V_{SS} (ground): + 15 to - 0.3V

Voltage to any input with respect to V_{SS} = + 15 to - 0.3V

I_{CC} = 60 MA (35 MA nominal)

I_{DD} = 15 MA (10 MA nominal)

C_{IN} & C_{OUT} = 15 pF max with all pins grounded except one under test.

Operating temperature = 0°C to 70°C

Storage temperature = - 55°C to + 125°C

OPERATING CHARACTERISTICS (DC)

T_A = 0°C to 70°C, V_{DD} = + 12V \pm .6V, V_{SS} = 0V, V_{CC} = + 5V \pm .25V

SYMBOL	CHARACTERISTIC	MIN.	MAX.	UNITS	CONDITIONS
I_{IL}	Input Leakage		10	μA	$V_{IN} = V_{DD}^{**}$
I_{OL}	Output Leakage		10	μA	$V_{OUT} = V_{DD}$
V_{IH}	Input High Voltage	2.6		V	
V_{IL}	Input Low Voltage		0.8	V	
V_{OH}	Output High Voltage	2.8		V	$I_O = -100 \mu A$
V_{OL}	Output Low Voltage		0.45	V	$I_O = 1.6 mA^*$
P_D	Power Dissipation		0.6	W	

*1792 and 1794 $I_O = 1.0 mA$

**Leakage conditions are for input pins without internal pull-up resistors. Pins 22, 23, 33, 36, and 37 have pull-up resistors. See Tech Memo #115 for testing procedures.

See page 725 for ordering information.

FD179X Application Notes

INTRODUCTION

Over the past several years, the Floppy Disk Drive has become the most popular on-line storage device for mini and microcomputer systems. Its fast access time, reliability and low cost-per-bit ratio enables the Floppy Disk Drive to be *the* solution in mass storage for microprocessor systems. The drive interface to the Host system is standardized, allowing the OEM to substitute one drive for another with minimum hardware/ software modifications.

Since Floppy Disk Data is stored and retrieved as a self-clocking serial data stream, some means of separating the clock from the data and assembling this data in parallel form must be accomplished. Data is stored on individual Tracks of the media, requiring control of a stepper motor to move the Read/Write head to a predetermined Track. Byte synchronization must also be accomplished to insure that the parallel data is properly assembled. After all the design considerations are met, the final controller can consist of 40 or more TTL packages.

To alleviate the burden of Floppy Disk Controller design, Western Digital has developed a Family of LSI Floppy Disk controller devices. Through its own set of macro commands, the FD179X Controller Family will perform all the functions necessary to read and write data to the drive. Both the 8" standard and 5¼" mini-floppy are supported with single or double density recording techniques. The FD179X is compatible with the IBM 3740 (FM) data format, or the System 34 (MFM) standards. Provisions for non-standard formats and variable sector lengths have been included to provide more storage capability per track. Requiring standard +5, +12 power supplies the FD179X is available in a standard 40 pin dual-in-line package.

The FD179X Family consists of 6 devices. The differences between these devices is summarized in Figure 1. The 1792 and 1794 are "single density only" devices, with the Double Density Enable pin (DDEN) left open by the user. Both True and inverted Data bus devices are available. Since the 179X can only drive one TTL Load, a true data bus system may use the 1791 with external inverting buffers to arrive at a true bus scheme. The 1795 and 1797 are identical to the 1791 and 1793, except a side select output has been added that is controlled through the Command Register.

SYSTEM DESIGN

The first consideration in Floppy Disk Design is to determine which type of drive to use. The choice ranges from single-density single sided mini-floppy to the 8" double-density double-sided drive. Figure 2 illustrates the various drive and data capacities associated with each type. Although the 8" double-density drive offers twice as much storage, a more complex data separator and the addition of Write Precompensation circuits are mandatory for reliable data transfers. Whether to go with 8" double-density or not is dependent upon PC board space and the additional circuitry needed to accurately recover data with extreme bit shifts. The byte transfer time defines the nominal time required to transfer one byte of data from the drive. If the CPU used cannot service a byte in this time, then a DMA scheme will probably be required. The 179X also needs a few microseconds for overhead, which is subtracted from the transfer time. Figure 3 shows the actual service times that the CPU must provide on a byte-by-byte basis. If these times are not met, bytes of data will be lost during a read or write operation. For each byte transferred, the 179X generates a DRQ (Data Request) signal on Pin 38. A bit is provided in the status register which is also set upon receipt of a byte from the Disk. The user has the option of reading the status register through program control or using the DRQ Line with DMA or interrupt schemes. When the data register is read, both the status register DRQ bit and the DRQ Line are automatically reset. The next full byte will again set the DRQ and the process continues until the sector(s) are read. The Write operation works exactly the same way, except a WRITE to the Data Register causes a reset of both DRQ's.

RECORDING FORMATS

The FD179X accepts data from the disk in a Frequency-Modulated (FM) or Modified-Frequency-Modulated (MFM) Format. Shown in Figures 4A and 4B are both these Formats when writing a Hexidecimal byte of 'D2'. In the FM mode, the 8 bits of data are broken up into "bit cells." Each bit cell begins with a clock pulse and the center of the bit cell defines the data. If the data bit = 0, no pulse is written; if the data = 1, a pulse is written in the center of the cell. For the 8" drive, each clock is written 4 microseconds apart.

In the MFM mode, clocks are decoded into the data stream. The byte is again broken up into bit cells, with the data bit written in the center of the bit cell if data = 1. Clocks are only written if both surrounding data bits are zero. Figure 4B shows that this occurs only once between Bit cell 4 and 5. Using this encoding scheme, pulses can occur 2, 3 or 4 microseconds apart. The bit cell time is now 2 microseconds; twice as much data can be recorded without increasing the Frequency rate due to this encoding scheme.

The 179X was designed to be compatible with the IBM 3740 (FM) and System 34 (MFM) Formats. Although most users do not have a need for data exchange with IBM mainframes, taking advantage of these well studied formats will insure a high degree of system performance. The 179X will allow a change in gap fields and sector lengths to increase usable storage capacity, but variations away from these standards is not recommended. Both IBM standards are soft-sector format. Because of the wide variation in address marks, the 179X can only support soft-sectored media. Hard sectored diskettes have continued to lose popularity, mainly due to the unavailability of a standard and the limitation of sector lengths imposed by the physical sector holes in the diskette.

PROCESSOR INTERFACE

The Interface of the 179X to the CPU consists of an 8-bit Bi-directional bus, read/write controls and optional interrupt lines. By selecting the device via the CHIP SELECT Line, each of the five internal registers can be accessed.

Shown below are the registers and their addresses:

PIN 3 CS	PIN 6 A ₁	PIN 5 A ₀	PIN 4 RE=Ø	PIN 2 WE=Ø
0	0	0	STATUS REG	COMMAND REG
0	0	1	TRACK REG	REG
0	1	0	SECTOR REG	TRACK REG
0	1	1	DATA REG	SECTOR REG
1	X	X	H1-Z	DATA REG H1-Z

Each time a command is issued to the 179X, the Busy bit is set and the INTRQ (Interrupt Request) Line is reset. The user has the option of checking the busy bit or use the INTRQ Line to denote command completion. The Busy bit will be reset whenever the 179X is idle and awaiting a new command. The INTRQ Line, once set, can only be reset by a READ of the status register or issuing a new command. The MR (Master Reset) Line does not affect INTRQ.

The A₀, A₁ Lines used for register selections can be configured at the CPU in a variety of ways. These lines may actually tie to CPU address lines, in which case the 179X will be memory-mapped and addressed like RAM. They may also be used under Program Control by tying to a port device such as the 8255, 6820, etc. As a diagnostic tool when checking out the CPU interface, the Track and Sector registers should respond like "RAM" when the 179X is idle (Busy = INTRQ = 0).

Because of internal synchronization cycles, certain time delays must be introduced when operating under Programmed I/O. The worst case delays are:

OPERATION	NEXT OPERATION	DELAY REQ'D
WRITE TO COMMAND REG	READ STATUS REGISTER	MFM = 14µs* FM = 28µs.
WRITE TO ANY REGISTER	READ FROM A DIFFERENT REG	NO DELAY

*NOTE: Times Double when CLK = 1MHz (5¼" drive)

Other CPU interface lines are CLK, \overline{MR} and \overline{DDEN} . The CLK line should be 2MHz (8" drive) or 1MHz (5¼" drive) with a 50% duty cycle. Accuracy should be $\pm 1\%$ (crystal source) since all internal timing, including stepping rates, are based upon this clock.

The \overline{MR} or Master Reset Line should be strobed a minimum of 50 microseconds upon each power-on condition. This line clears and initializes all internal registers and issues a restore command (Hex '03') on the rising edge. A quicker stepping rate can be written to the command register after a \overline{MR} , in which case the remaining steps will occur at the faster programmed rate. The 179X will issue a maximum of 255 stepping pulses in an attempt to expect the TROO line to go active low. This line should be connected to the drive's TROO sensor.

The \overline{DDEN} line causes selection of either single density ($\overline{DDEN} = 1$) or double density operation. \overline{DDEN} should not be switched during a read or write operation.

FLOPPY DISK INTERFACE

The Floppy Disk Interface can be divided into three sections: Motor Control, Write Signals and Read Signals. All of these lines are capable of driving one TTL load and not compatible for direct connection to the drive. Most drives require an open-collector TTL interface with high current drive capability. This must be done on all outputs from the 179X. Inputs to the 179X may be buffered or tied to the Drives outputs, providing the appropriate resistor termination networks are used. Undershoot should not exceed -0.3 volts, while integrity of V_{IH} and V_{OH} levels should be kept within spec.

MOTOR CONTROL

Motor Control is accomplished by the STEP and DIRC Lines. The STEP Line issues stepping pulses with a period defined by the rate field in all Type I commands. The DIRC Line defines the direction of steps (DIRC = 1 STEP IN/DIRC = 0 STEP OUT).

Other Control Lines include the \overline{IP} or Index Pulse. This Line is tied to the drives' Index L.E.D. sensor and makes an active transition for each revolution of the diskette. The TROO Line is another L.E.D. sensor that informs the 179X that the stepper motor is at its furthest position, over Track 00. The READY Line can be used for a number of functions, such as sensing "door open", Drive motor on, etc. Most drives provide a programmable READY Signal selected by option jumpers on the drive. The 179X will look at the ready signal prior to executing READ/WRITE commands. READY is not inspected during any Type I commands. All Type I commands will execute regardless of the Logic Level on this Line.

WRITE SIGNALS

Writing of data is accomplished by the use of the WD, WG, WF, TG43, EARLY and LATE Lines. The WG or Write Gate Line is used to enable write current at the drive's R/W head. It is made active prior to writing data on the disk. The WF or WRITE FAULT Line is used to inform the 179X of a failure in drive electronics. This signal is multiplexed with the VFOE Line and must be logically separated if required. Figure 5 illustrates three methods of demultiplexing.

The TG43 or "TRACK GREATER than 43" Line is used to decrease the Write current on the inner tracks, where bit densities are the highest. If not required on the drive, TG43 may be left open.

WRITE PRECOMPENSATION

The 179X provides three signals for double density Write Precompensation use. These signals are WRITE DATA, EARLY and LATE. When using single density drives (eighther 8" or 5 $\frac{1}{4}$ "), Write Precompensation is not necessary and the WRITE DATA line is generally TTL Buffered and sent directly to the drive. In this mode, EARLY and LATE are left open.

For double density use, Write Precompensation is a function of the drive. Some manufacturers recommend Precompensating the 5 $\frac{1}{4}$ " drive, while others do not.

With the 8" drive, Precompensation may be specified from TRACK 43 on, or in most cases, all TRACKS. If the recommended Precompensation is not specified, check with the manufacturer for the proper configuration required.

The amount of Precompensation time also varies. A typical value will usually be specified from 100-300ns. Regardless of the parameters used, Write Precompensation must be done external to the 179X. When \overline{DDEN} is tied low, EARLY or LATE will be activated at least 125ns. before and after the Write Data pulse. An Algorithm internal the 179X decides whether to raise EARLY or LATE, depending upon the previous bit pattern sent. As an example, suppose the recommended Precomp value has been specified at 150ns. The following action should be taken:

EARLY	LATE	ACTION TAKEN
0	0	delay WD by 150ns (nominal)
0	1	delay WD by 300ns (2X value)
1	0	do not delay WD

There are two methods of performing Write Precompensation:

- 1) External Delay elements
- 2) Digitally

Shown in Figure 6 is a Precomp circuit using the Western Digital 2143 clock generator as the delay element. The WD pulse from the 179X creates a strobe to the 2143, causing subsequent output pulses on the ϕ_1 , ϕ_2 and ϕ_3 signals. The 5K Precomp adjust sets the desired Precomp value. Depending upon the condition of EARLY and LATE, ϕ_1 will be used for EARLY, ϕ_2 for nominal (EARLY = LATE = 0), and ϕ_3 for LATE. The use of "one-shots" or delay line in a Write Precompensation scheme offers the user the ability to vary the Precomp value. The ϕ_4 output resets the 74LS175 Latch in anticipation of the next WD pulse. Figure 7 shows the WD-EARLY/LATE relationship, while Figure 8 shows the timing of this write Precomp scheme.

Another method of Precomp is to perform the function digitally. Figure 9 illustrates a relationship between the WD pulse and the CLK pin, allowing a digital Precomp scheme. Figure 10 shows such a scheme with a preset Write Precompensation value of 250ns. The synchronous counter is used to generate 2MHz and 4MHz clock signals. The 2MHz clock is sent to the CLK input of the 179X and the 4MHz is used by the 4-bit shift register. When a WD pulse is not present, the 4MHz clock is shifting "ones" through the shift register and maintaining Q_D at a zero level. When a WD pulse is present, a zero is loaded at either A, B, or C depending upon the states of LATE, EN PRECOMP and EARLY. The zero is then shifted by the 4MHz clock until it reaches the Q_D output. The number of shift operations determines whether the WRITE DATA pulse is written early, nominal or late. If both FM and MFM operations is a system requirement, the output of this circuit should be disabled and the WD pulse should be sent directly to the drive.

DATA SEPARATION

The 179X has two inputs (RAW READ & RCLK) and one output (VFOE) for use by an external data separator. The RAW READ input must present clock and data pulses to the 179X, while the RCLK input provides a "window" or strobe signal to clock each RAW READ pulse into the device. An ideal Data Separator would have the leading edge of the RAW READ pulse occur in the exact center of the RCLK strobe.

Motor Speed Variation, Bit shifts and read amplifier recovery circuits all cause the RAW READ pulses to drift away from their nominal positions. As this occurs, the RAW READ pulses will shift left or right with respect to RCLK. Eventually, a pulse will make its transition outside of its RCLK window, causing either a CRC error or a Record-not-Found error at the 179X.

A Phase-Lock-Loop circuit is one method of achieving synchronization between the RCLK and RAW READ signals. As RAW READ pulses are fed to the PLL, minor adjustments of the free-running RCLK frequency can be made. If pulses are occurring too far apart, the RCLK frequency is *decreased* to keep synchronization. If pulses begin to occur closer together, RCLK is *increased* until this new higher frequency is achieved. In normal read operations, RCLK will be constantly adjusted in an attempt to match the incoming RAW READ frequency.

Another method of Data Separation is the Counter-Separator technique. The RCLK signal is again free-running at a nominal rate, until a RAW READ pulse occurs. The Separator then denotes the position of the pulse with respect to RCLK (by the counter value), and counts down to increase or decrease the current RCLK window. The next RCLK window will occur at a nominal rate and will continue to run at this frequency until another RAW READ pulse adjusts RCLK, but only the present window is adjusted.

Both PPL and Counter/Separator are acceptable methods of Data Separation. The PPL has the highest reliability because of its "tracking" capability and is recommended for 8" double density designs.

As a final note, the term "Data Separator" may be misleading, since the physical separation of clock and data bits are not actually performed. This term is used throughout the industry, and can better be described as a "Data Recovery Circuit" rather than a Data Separator.

The VFOE signal is an output from the 179X that signifies the head has been loaded and valid data pulses are appearing on the RAW READ line. It can be used to enable the Data Separator and to insure clean RCLK transitions to the 179X. Since some drives will output random pulses when the head is disengaged, VFOE can prevent an erratic RCLK signal during this time. If the Data Separator requires synchronization during a known pattern of one's or zero's, then RG (READ GATE) can be used. The RG signal will go active when the 179X is currently over a field of zeros or ones. RG is not available on the 1795/1797 devices, since this signal was replaced with the SSO (Side Select Output) Line.

Shown in Figure 11 is a 2½ IC Counter/Separator. The 74LS193 free runs at a frequency determined by the CRYCLK input. When a RAW READ pulse occurs, the counter is loaded with a starting count of '5'. When the RAW READ Line returns to a Logic 1, the counter counts down to zero and again free runs. The 74LS74 insures a 50% duty cycle to the 179X and performs a divide-by-two of the Q_D output.

Figure 12 illustrates another Counter/Separator utilizing a PROM as the count generator. Depending upon the RAW READ phase relationship to RCLK, the PROM is addressed and its data output is used as the counter value. A 16MHz clock is required for 8" double density, while an 8MHz clock can be used for single density.

Figure 13 shows a Phase-Lock-Loop data recovery circuit. The phase detector (U2, Figure 2) compares the phase of the SHAPED DATA pulse to the phase of VFO CLK ÷ 2. If VFO CLK ÷ 2 is lagging the SHAPED DATA pulse an output pulse on #9, U2 is generated. The filter/amplifier converts this pulse into a DC signal which increases the frequency of the VCO.

If, correspondingly, CLK ÷ 2 is leading the SHAPED DATA pulse, an output pulse on #5, U2 is generated. This pulse is converted into a DC signal which decreases the frequency of the VCO. These two actions cause the VCO to track the frequency of the incoming READ DATA pulses. This correction process to keep the two signals in phase is constantly occurring because of spindle speed variation and circuit parameter variations.

The operating specifications for this circuit are as follows:

Free Running Frequency	2MHz
Capture Range	± 15%
Lock Up Time	50 microsec. "1111" or "0000" Pattern
	100 Microsec "1010" Pattern

The RAW READ pulses are generated from the falling edge of the SHAPED DATA pulses. The pulses are also reshaped to meet the 179X requirements. VFO CLK ÷ 2 OR 4 is divided by 2 once again to obtain VFO CLK OUT whose frequency is that required by the 179X RCLK input. RCLK must be controlled by VFOE so VFOE is sampled on each rising edge of VFO CLK OUT. When VFOE goes active EN RCLK goes active in synchronization with VFO CLK OUT preventing any glitches on the RCLK output. When VFOE goes inactive EN RCLK goes inactive in synchronization with VFO CLK OUT, again preventing any glitches on the RCLK output.

Figure 14 illustrates a PPL data recovery circuit using the Western Digital 1691 Floppy Support device. Both data recovery and Write Precomp Logic is contained within the 1691, allowing low chip count and PLL reliability. The 74S124 supplies the free-running VCO output. The PUMP UP and PUMP DOWN signals from the 1691 are used to control the 74S124's frequency.

COMMAND USAGE

Whenever a command is successfully or unsuccessfully completed, the busy bit of the status register is reset and the INTRQ line is forced high. Command termination may be detected either way. The INTRQ can be tied to the host processor's interrupt with an appropriate service routine to terminate commands. The busy bit may be monitored with a user program and will achieve the same results through software. Performing both an INTRQ and a busy bit check is not recommended because a read of the status register to determine the condition of the busy bit will reset the INTRQ line. This can cause an INTRQ from not occurring.

RESTORE COMMAND

On some disk drives, it is possible to position the R/W head outward past Track 00 and prevent the TROO line from going low unless a STEP IN is first performed. If this condition exists in the drive used, the RESTORE command will never detect a TROO. Issuing several STEP IN pulses before a RESTORE command will remedy this situation. The RESTORE and all other Type I commands will execute even though the READY bit indicates the drive is not ready (NOT READY = 1).

READ TRACK COMMAND

The READ TRACK command can be used to manually inspect data on a hard copy printout. Gaps, address marks and all data are brought in to the data register during this command. The READ TRACK command may be used to inspect diskettes for valid formatting and data fields as well as address marks. Since the 179X does not synchronize clock and data until the Index Address Mark is detected, data previous to this ID mark will not be valid. READ GATE (RG) is not actuated during this command.

READ ADDRESS COMMAND

In systems that use either multiple drives or sides, the read address command can be used to tell the host processor which drive or side is selected. The current position of the R/W head is also denoted in the six bytes of data that are sent to the computer.

TRACK	SIDE	SECTOR	CRS LENGTH	CRC 1	CRC 2
-------	------	--------	---------------	----------	----------

The READ ADDRESS command as well as all other Type II and Type III commands will not execute if the READY line is inactive (READY = 0). Instead, an interrupt will be generated and the NOT READY status bit will be set to a 1.

FORCED INTERRUPT COMMAND

The Forced Interrupt command is generally used to terminate a multiple sector command or to insure Type I status in the status register. The lower four bits of the command determine the conditional interrupt as follows:

1 ₀	=	NOT-READY TO READY TRANSITION
1 ₁	=	READY TO NOT-READY TRANSITION
1 ₂	=	EVERY INDEX PULSE
1 ₃	=	IMMEDIATE INTERRUPT

Regardless of the conditional interrupt set, any command that is currently being executed when the Forced Interrupt command is loaded will immediately be terminated and the busy bit will be reset indicating an idle condition.

Then, when the condition for interrupt is met, the INTRQ line will go high signifying that the condition specified has occurred.

The conditional interrupt is enabled when the corresponding bit positions of the command (1₃ - 1₀) are set to a 1. If 1₃ - 1₀ are all set to zero, no interrupt will occur, but any command presently under execution will be immediately terminated upon receipt of the Force Interrupt command (HEX DO).

As usual, to clear the interrupt a read of the status register or a write to the command register is required. The exception is when using the immediate interrupt condition (1₃ = 1). If this command is loaded into the command register, an interrupt will be immediately generated and the current command terminated. Reading the status or writing to the command register will not automatically clear the interrupt; another forced interrupt command with 1₃ - 1₀ = 0 must be loaded into the command register in order to reset the INTRQ from this condition.

More than one condition may be set at a time. If for example, the READY TO NOT-READY condition (1₁ = 1) and the Every Index Pulse (1₂ = 1) are both set, the resultant command would be HEX "DA". The "OR" function is performed so that either a READY TO NOT-READY or the next Index Pulse will cause an interrupt condition.

DATA RECOVERY

Occasionally, the R/W head of the disk drive may get "off track", and dust or dirt may get trapped on the media. Both of these conditions will cause a RECORD NOT FOUND and/or a CRC error to occur. This "soft error" can usually be recovered by the following procedure:

1. Issue the command again
2. Unload and load the head and repeat step
3. Issue a restore, seek the track, and repeat step 1

If RNF or CRC errors are still occurring after trying these methods, a "hard error" may exist. This is usually caused by improper disk handling, exposure to high magnetic fields, etc. and generally results in destroying portions or tracks of the diskette.

WD279X-02 Floppy Disk Formatter/Controller Family

FEATURES

- ON-CHIP PLL DATA SEPARATOR
- ON-CHIP WRITE PRECOMPENSATION LOGIC
- SINGLE +5V SUPPLY
- ACCOMMODATES SINGLE AND DOUBLE DENSITY FORMATS
 - IBM 3740 (FM)
 - IBM 34 (MFM)
- AUTOMATIC SEEK WITH VERIFY
- MULTIPLE SECTOR READ/WRITE
- TTL COMPATIBLE
- PROGRAMMABLE CONTROL
 - SELECTABLE TRACK-TO-TRACK ACCESS
 - HEAD LOAD TIMING
- SOFTWARE COMPATIBLE WITH THE FD179X SERIES
- SOFT SECTOR FORMAT COMPATIBILITY

APPLICATIONS

8" FLOPPY AND 5¼" MINI FLOPPY CONTROLLER
SINGLE OR DOUBLE DENSITY
CONTROLLER/FORMATTER

The WD279X Family are MOS/LSI devices which perform the functions of a Floppy Disk Controller/Formatter. Software compatible with its predecessor, the FD179X, the device also contains a high performance Phase-Lock-Loop Data Separator as well as Write Precompensation Logic.

When operating in Double Density mode, Write Precompensation is automatically engaged to a value programmed via an external potentiometer. An on-chip VCO and phase comparator allows adjustable frequency range for 5¼" or 8" Floppy Disk interfacing.

The WD279X is fabricated in NMOS silicon gate technology and available in a 40 pin dual-in-line ceramic or plastic package.

FEATURES	2791	2793	2795	2797

PIN OUTS

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION																									
1	ENABLE PRECOMP	ENP	A Logic high on this input enables write precompensation to be performed on the Write Data output.																									
19	MASTER RESET	MR	A logic low (50 microseconds min.) on this input resets the device and loads HEX 03 into the command register. The Not Ready (Status Bit 7) is reset during MR ACTIVE. When MR is brought to a logic high a RESTORE Command is executed, regardless of the state of the Ready signal from the drive. Also, HEX 01 is loaded into sector register.																									
20	POWER SUPPLIES	VSS	Ground																									
21		VCC	+5V ± 5%																									
COMPUTER INTERFACE:																												
2	WRITE ENABLE	WE	A logic low on this input gates data on the DAL into the selected register when CS is low.																									
3	CHIP SELECT	CS	A logic low on this input selects the chip and enables computer communication with the device.																									
4	READ ENABLE	RE	A logic low on this input controls the placement of data from a selected register on the DAL when CS is low.																									
5,6	REGISTER SELECT LINES	A0, A1	These inputs select the register to receive/transfer data on the DAL lines under RE and WE control: <table><tr><td>CS</td><td>A1</td><td>A0</td><td>RE</td><td>WE</td></tr><tr><td>0</td><td>0</td><td>0</td><td>Status Reg</td><td>Command Reg</td></tr><tr><td>0</td><td>0</td><td>1</td><td>Track Reg</td><td>Track Reg</td></tr><tr><td>0</td><td>1</td><td>0</td><td>Sector Reg</td><td>Sector Reg</td></tr><tr><td>0</td><td>1</td><td>1</td><td>Data Reg</td><td>Data Reg</td></tr></table>	CS	A1	A0	RE	WE	0	0	0	Status Reg	Command Reg	0	0	1	Track Reg	Track Reg	0	1	0	Sector Reg	Sector Reg	0	1	1	Data Reg	Data Reg
CS	A1	A0	RE	WE																								
0	0	0	Status Reg	Command Reg																								
0	0	1	Track Reg	Track Reg																								
0	1	0	Sector Reg	Sector Reg																								
0	1	1	Data Reg	Data Reg																								
7-14	DATA ACCESS LINES	DAL0-DAL7	Eight bit bi-directional bus used for transfer of commands, status, and data. These lines are inverted (active low) on WD2791 and WD2795.																									
24	CLOCK	CLK	This input requires a free-running 50% duty cycle square wave clock for internal timing reference, 2 MHz ± 1% for 8" drives, 1 MHz ± 1% for mini-floppies.																									
38	DATA REQUEST	DRQ	This output indicates that the Data Register contains assembled data in Read operations, or the DR is empty in Write operations. This signal is reset when serviced by the computer through reading or loading the DR.																									
39	INTERRUPT REQUEST	INTRQ	This output is set at the completion of any command and is reset when the Status register is read or the Command register is written to.																									
FLOPPY DISK INTERFACE:																												
15	STEP	STEP	The step output contains a pulse for each step.																									
16	DIRECTION	DIRC	Direction Output is active high when stepping in, active low when stepping out.																									
17	5¼," 8" SELECT	5/8	This input selects the internal VCO frequency for use with 5¼" drives or 8" drives.																									
18	READ PULSE WIDTH	RPW	An external potentiometer tied to this input controls the phase comparator within the data separator.																									

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
22	TEST	TEST	A logic low on this input allows adjustment of external resistors by enabling internal signals to appear on selected pins.
23	PUMP	PUMP	High-Impedance output signal which is forced high or low to increase/decrease the VCO frequency.
25	ENABLE MINI-FLOPPY (2791, 2793)	ENMF	A logic low on this input enables an internal +2 of the Master Clock when $\overline{S}/8$ is also at a logic 0. This allows both 5¼" and 8" drive operation with a single 2 MHz clock. For a 1 MHz clock on Pin 24, this line must be left open or tied to a Logic 1.
25	SIDE SELECT OUTPUT (2795, 2797)	SSO	The logic level of the Side Select Output is directly controlled by the 'S' flag in Type II or III commands. When U = 1, SSO is set to a logic 1. When U = 0, SSO is set to a logic 0. The SSO is compared with the side information in the Sector I.D. Field. If they do not compare Status Bit 4 (RNF) is set. The Side Select Output is only updated at the beginning of a Type II or III command. It is forced to a logic 0 upon a MASTER RESET condition.
26	VOLTAGE-CONTROLLED OSCILLATOR	VCO	An external capacitor tied to this pin adjusts the VCO center frequency.
27	RAW READ	RAW READ	The data input signal directly from the drive. This input shall be a negative pulse for each recorded flux transition.
28	HEAD LOAD	HLD	The HLD output controls the loading of the Read-Write head against the media.
29	TRACK GREATER THAN 43	TG43	This output informs the drive that the Read/Write head is positioned between tracks 44-76. This output is valid only during Read and Write Commands.
30	WRITE GATE	WG	This output is made valid before writing is to be performed on the diskette.
31	WRITE DATA	WD	A 250ns (MFM) or 500 ns (FM) output pulse per flux transition. WD contains the unique Address marks as well as data and clock in both FM and MFM formats.
32	READY	READY	This input indicates disk readiness and is sampled for a logic high before Read or Write commands are performed. If Ready is low the Read or Write operation is not performed and an interrupt is generated. Type I operations are performed regardless of the state of Ready. The Ready input appears in inverted format as Status Register bit 7.
33	WRITE PRECOMP WIDTH	WPW	An external potentiometer tied to this input controls the amount of delay in Write precompensation mode.
34	TRACK 00	TR00	This input informs the WD279X that the Read/Write head is positioned over Track 00.
35	INDEX PULSE	IP	This input informs the WD279X when the index hole is encountered on the diskette.

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION
36	WRITE PROTECT	WPRT	This input is sampled whenever a Write Command is received. A logic low terminates the command and sets the Write Protect Status bit.
37	DOUBLE DENSITY	DDEN	This input pin selects either single or double density operation. When $\overline{\text{DDEN}} = 0$, double density is selected. When $\overline{\text{DDEN}} = 1$, single density is selected.
40	HEAD LOAD TIMING	HLT	When a logic high is found on the HLT input the head is assumed to be engaged. It is typically derived from a 1 shot triggered by HLD.

GENERAL DESCRIPTION

The WD279X are N-Channel Silicon Gate MOS LSI devices which perform the functions of a Floppy Disk Formatter/Controller in a single chip implementation. The WD279X, which can be considered the end result of both the FD1771 and FD179X designs, is IBM 3740 compatible in single density mode (FM) and System 34 compatible in Double Density Mode (MFM). The WD279X contains all the features of its predecessor the FD179X plus a high performance Phase-Lock-Loop Data Separator as well as Write Precompensation Logic. In Double Density mode, Write Precompensation is automatically engaged to a value programmed via an external potentiometer. In order to maintain compatibility, the FD1771, FD179X and WD279X designs were made as close as possible with the computer interface, instruction set, and I/O registers being identical. Also, head load control is identical. In each case, the actual pin assignments vary by only a few pins from any one to another.

The processor interface consists of an 8-bit bi-directional bus for data, status, and control word transfers. The WD279X is set up to operate on a multiplexed bus with other bus-oriented devices.

The WD279X is TTL compatible on all inputs and outputs. The outputs will drive one TTL load or three LS loads. The 2793 is identical to the 2791 except the DAL lines are TRUE for systems that utilize true data busses.

The 2795/7 has a side select output for controlling double sided drives.

ORGANIZATION

The Floppy Disk Formatter block diagram is illustrated on page 5. The primary sections include the parallel processor interface and the Floppy Disk interface.

Data Shift Register — This 8-bit register assembles serial data from the Read Data input ($\overline{\text{RAW READ}}$) during Read operations and transfers serial data to the Write Data output during Write operations.

Data Register — This 8-bit register is used as a holding register during Disk Read and Write operations in Disk Read operations the assembled data byte is transferred in parallel to the Data Register from the Data Shift Register. In Disk Write operations information is transferred in parallel from the Data Register to the Data Shift Register.

When executing the Seek command the Data Register holds the address of the desired Track position. This

register is loaded from the DAL and gated onto the DAL under processor control.

Track Register — This 8-bit register holds the track number of the current Read/Write head position. It is incremented by one every time the head is stepped in (towards track 76) and decremented by one when the head is stepped out (towards track 00). The contents of the register are compared with the recorded track number in the ID field during disk Read, Write and Verify operations. The Track Register can be loaded from or transferred to the DAL. This Register should not be loaded when the device is busy.

Sector Register (SR) — This 8-bit register holds the address of the desired sector position. The contents of the register are compared with the recorded sector number in the ID field during disk Read or Write operations. The Sector Register contents can be loaded from or transferred to the DAL. This register should not be loaded when the device is busy.

Command Register (CR) — This 8-bit register holds the command presently being executed. This register should not be loaded when the device is busy unless the new command is a force interrupt. The command register can be loaded from the DAL, but not read onto the DAL.

Status Register (STR) — This 8-bit register holds device Status information. The meaning of the Status bits is a function of the type of command previously executed. This register can be read onto the DAL, but not loaded from the DAL.

CRC Logic — This logic is used to check or to generate the 16-bit Cyclic Redundancy Check (CRC). The polynomial is: $G(x) = x^{16} + x^{12} + x^5 + 1$.

The CRC includes all information starting with the address mark and up to the CRC characters. The CRC register is preset to ones prior to data being shifted through the circuit.

Arithmetic/Logic Unit (ALU) — The ALU is a serial comparator, incrementer, and decremter and is used for register modification and comparisons with the disk recorded ID field.

Timing and Control — All computer and Floppy Disk interface controls are generated through this logic. The internal device timing is generated from an external crystal clock.

AM Detector — The address mark detector detects ID, data and index address marks during read and write operations.

Write Precompensation — enables write precompensation to be performed on the Write Data output.

Data Separator — a high performance Phase-Lock-Loop Data Separator with on-chip VCO and phase comparator allows adjustable frequency range for 5¼" or 8" Floppy Disk interfacing.

The interface to the processor is accomplished through the eight Data Access Lines (DAL) and associated control signals. The DAL are used to transfer Data, Status, and Control words out of, or into the WD279X. The DAL are three state buffers that are enabled as output drivers when Chip Select (\overline{CS}) and Read Enable (\overline{RE}) are active (low logic state) or act as input receivers when \overline{CS} and Write Enable (\overline{WE}) are active.

At the completion of every command an INTRQ is generated. INTRQ is reset by either reading the status register or by loading the command register with a new command. In addition, INTRQ is generated if a Force Interrupt command condition is met.

215

The 279X has two modes of operation according to the state of $\overline{\text{DDEN}}$ (Pin 37). When $\overline{\text{DDEN}} = 1$, Single Density (FM) is selected. When $\overline{\text{DDEN}} = 0$, Double Density (MFM) is selected. In either case, the CLK input (Pin 24) is set at 2 MHz for 8" drives or 1 MHz for 5¼" drives.

On the 2791/2793, the $\overline{\text{ENMF}}$ input (Pin 25) can be used for controlling both 5¼" and 8" drives with a single 2 MHz clock. When $\overline{\text{ENMF}} = 0$, an internal $\div 2$ of the CLK is performed. When $\overline{\text{ENMF}} = 1$, no divide takes place. This allows the use of a 2 MHz clock for both 5¼" and 8" configurations.

The internal VCO frequency must also be set to the proper value. The $\overline{5/8}$ input (Pin 17) is used to select data separator operation by internally dividing the Read Clock. When $\overline{5/8} = 0$, 5¼" data separation is selected; when $\overline{5/8} = 1$, 8" drive data separation is selected.

CLOCK (24)	$\overline{\text{ENMF}}$ (25)	$\overline{5/8}$ (17)	DRIVE
2 MHz	1	1	8"
2 MHz	0	0	5¼"
1 MHz	1	0	5¼"

Note: All other conditions invalid.

FUNCTIONAL DESCRIPTION

The WD279X-02 is software compatible with the FD179X-02 series of Floppy Disk Controllers. Commands, status, and data transfers are performed in the same way. Software generated for the 179X can be transferred to a 279X system without modification.

In addition to the 179X, the 279X contains an internal Data Separator and Write precompensation circuit. The $\overline{\text{TEST}}$ (Pin 22) line is used to adjust both data separator and precompensation. When $\overline{\text{TEST}} = 0$, the WD (Pin 31) line is internally connected to the output of the write precomp one-shot. Adjustment of the WPW (Pin 33) line can then be accomplished. A second one-shot tracks the precomp setting at approximately 3:1 to insure adequate Write Data pulse widths to meet drive specifications.

Similarly, Data separation is also adjusted with $\overline{\text{TEST}} = 0$. The TG43 (Pin 29) line is internally connected to the output of the read data one-shot, which is adjusted via the RPW (Pin 18) line. The DIRC (Pin 16) line contains the Read Clock output (5 MHz for 8" drives). The VCO Trimming capacitor (Pin 26) is adjusted for center frequency.

Internal timing signals are used to generate pulses during the adjustment mode so that these adjustments can be made while the device is in-circuit. The $\overline{\text{TEST}}$ line also contains a pull-up resistor, so adjustments can be performed simply by grounding the $\overline{\text{TEST}}$ pin, overriding the pull-up. The $\overline{\text{TEST}}$ pin cannot be used to disable stepping rates during operation as its function is quite different from the 179X.

Other pins on the device also include pull-up resistors and may be left open to satisfy a Logic 1 condition. These are: ENP, $\overline{5/8}$, $\overline{\text{ENMF}}$, $\overline{\text{WPRT}}$, and $\overline{\text{DDEN}}$.

GENERAL DISK READ OPERATIONS

Sector lengths of 128, 256, 512 or 1024 are obtainable in either FM or MFM formats. For FM, $\overline{\text{DDEN}}$ should be placed to logical "1." For MFM formats, $\overline{\text{DDEN}}$ should be

Sector Length Table*	
Sector Length Field (hex)	Number of Bytes in Sector (decimal)
00	128
01	256
02	512
03	1024

* 2795/97 may vary — see command summary.

placed to a logical "0." Sector lengths are determined at format time by the fourth byte in the "ID" field.

The number of sectors per track as far as the 279X is concerned can be from 1 to 255 sectors. The number of tracks as far as the 279X is concerned is from 0 to 255 tracks. For IBM 3740 compatibility, sector lengths are 128 bytes with 26 sectors per track. For System 34 compatibility (MFM), sector lengths are 256 bytes/sector with 26 sectors/track; or lengths of 1024 bytes/sector with 8 sectors/track.

GENERAL DISK WRITE OPERATION

When writing is to take place on the diskette the Write Gate (WG) output is activated, allowing current to flow into the Read/Write head. As a precaution to erroneous writing the first data byte must be loaded into the Data Register in response to a Data Request from the 279X before the Write Gate signal can be activated.

Writing is inhibited when the $\overline{\text{Write Protect}}$ input is a logic low, in which case any Write command is immediately terminated, an interrupt is generated and the Write Protect status bit is set.

For write operations, the 279X provides Write Gate (Pin 30) and Write Data (Pin 31) outputs. Write data consists of a series of pulses set to a width approximately three times greater than the precomp adjustment. Write Data provides the unique address marks in both formats.

READY

Whenever a Read or Write command (Type II or III) is received the 279X samples the Ready input. If this input is logic low the command is not executed and an interrupt is generated. All Type I commands are performed regardless of the state of the Ready input. Also, whenever a Type II or III command is received, the TG43 signal output is updated. TG43 may be tied to ENP to enable write precompensation on tracks 44-76.

COMMAND DESCRIPTION

The WD279X will accept eleven commands. Command words should only be loaded in the Command Register when the Busy status bit is off (Status bit 0). The one exception is the Force interrupt command. Whenever a command is being executed, the Busy status bit is set. When a command is completed, an interrupt is generated and the Busy status bit is reset. The Status Register indicates whether the completed command encountered an error or was fault free. For ease of discussion, commands are divided into four types. Commands and types are summarized in Table 1.

TABLE 1. COMMAND SUMMARY

A. Commands for Models: 2791, 2793

B. Commands for Models: 2795, 2797

Type Command	Bits								Bits							
	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0

*NOTE: See Type IV Command Description for further information.

Write Precompensation

When operating in Double Density mode ($\overline{\text{DDEN}} = 0$), the 279X has the capability of providing a user-defined precompensation value for Write Data. An external potentiometer (10K) tied to the WPW signal (Pin 33) allows a setting of 100 to 300 ns from nominal.

Setting the Write precomp value is accomplished by forcing the $\overline{\text{TEST}}$ line (Pin 22) to a Logic 0. A stream of pulses can then be seen on the Write Data (Pin 31) line. Adjust the WPW Potentiometer for the desired pulse width. This adjustment may be performed in-circuit since Write Gate (Pin 30) is inactive while $\overline{\text{TEST}} = 0$.

Data Separation

The 279X can operate with either an external data separator or its own internal recovery circuits. The condition of the $\overline{\text{TEST}}$ line (Pin 22) in conjunction with $\overline{\text{MR}}$ (Pin 19) will select internal or external mode.

To program the 279X for external VCO, a $\overline{\text{MR}}$ pulse must be applied while $\overline{\text{TEST}} = 0$. A clock equivalent to eight times the data rate (e.g., 4.0 MHz for 8" Double Density) is applied to the VCO input (Pin 26). The feedback reference voltage is available on the Pump output (Pin 23) for external integration to control the VCO. $\overline{\text{TEST}}$ is returned to a Logic 1 for normal operation. Note: To maintain this mode, $\overline{\text{TEST}}$ must be held low whenever $\overline{\text{MR}}$ is applied.

For internal VCO operation, the $\overline{\text{TEST}}$ line must be high during the $\overline{\text{MR}}$ pulse, then set to a Logic 0 for the adjustment procedure.

A 50K Potentiometer tied to the RPW input (Pin 18) is used to set the internal Read Data pulse for proper phasing. With a scope on Pin 29 (TG43), adjust the RPW pulse for 1/8 of the data rate (250 ns for 8" Double Density). An external variable capacitor of 5-60 pf is tied to the VCO input (Pin 26) for adjusting center frequency. With a frequency counter on Pin 16 (DIRC) adjust the trimmer cap to yield the appropriate Data Rate (500 KHz for 8" Double Density). The $\overline{\text{DDEN}}$ line must be low while the 5/8 line is held high or the adjustment times above will be doubled.

After adjustments have been made, the $\overline{\text{TEST}}$ pin is returned to a Logic 1 and the device is ready for operation. Adjustments may be made in-circuit since the DIRC and TG43 lines may toggle without affecting the drive.

The PUMP output (Pin 23) consists of positive and negative pulses, which their duration is equivalent to the phase difference of incoming Data vs. VCO frequency. This signal is internally connected to the VCO input, but a Filter is needed to connect these pulses to a slow moving DC voltage.

The internal phase-detector is unsymmetrical for a random distribution of data pulses by a factor of two, in favor of a PUMP UP condition. Therefore, it is desirable to have a PUMP DOWN twice as responsive to prevent run-away during a lock attempt.

A first order lag-lead filter can be used at the PUMP output (Pin 23). This filter controls the instantaneous response of the VCO to bit-shifted data (jitter) as well as the response to normal frequency shift, i.e., the lock-up time. A balance must be accomplished between the two conditions to

inhibit over-responsiveness to jitter and to prevent an extremely wide lock-up response, leading to PUMP run-away. The filter affects these two reactions in mutually opposite directions.

The Source Impedance for a PUMP UP/DOWN condition is 600/120 ohms, respectively, therefore the change in bias voltage for each pump can be approximated:

$$\begin{aligned} dV &= \frac{dt \Delta V}{RC} & dt &= 250 \text{ ns. (set by RPW)} \\ & & C &= 0.1 \mu\text{f} \\ & & R &= R_S + R \\ \Delta V &= 2.6 \text{ V for PUMP UP} \\ & & & 0.9 \text{ V for PUMP DOWN} \end{aligned}$$

Lock

Lock-up response (T_L) is the transient time for the Loop to lock from center frequency (F_0) to maximum lock range:

$$T_L = 10\% F_L \times K_O \times \Delta P$$

Where:

K_O = VCO Conversion Gain = 3.7 KHz/mV

F_L = Lock Range = 4.00 MHz

ΔP = Change in Bias for each Pump = 4 mV/PUMP

$$400 \text{ KHz} \times 3.7 \text{ KHz} \times 4 \text{ mV} = 27 \text{ pumps}$$

$$27 \text{ pumps} = 54 \mu\text{sec} = 3.4 \text{ Byte times (8" Double Density)}$$

The following Filter Circuit is recommended for 8" FM/MFM:

Since 5 1/4" Drives operate at exactly one-half the data rate (250 Kb/sec) the above capacitor should be doubled to .2 or .22μf.

TYPE I COMMANDS

The Type I Commands include the Restore, Seek, Step, Step-in, and Step-Out commands. Each of the Type I Commands contains a rate field ($r_0 r_1$), which determines the stepping motor rate as defined in Table 3.

A 2μs (MFM) or 4 μs (FM) pulse is provided as an output to the drive. For every step pulse issued, the drive moves one track location in a direction determined by the direction output. The chip will step the drive in the same direction it last stepped unless the command changes the direction.

The Direction signal is active high when stepping in and low when stepping out. The Direction signal is valid 12 μs before the first stepping pulse is generated.

The rates (shown in Table 3) can be applied to a Step-Direction Motor through the device interface.

TABLE 3. STEPPING RATES

CLK		2 MHz	1 MHz
R1	R0	$\overline{\text{TEST}} = 1$	$\overline{\text{TEST}} = 1$
0	0	3 ms	6 ms
0	1	6 ms	12 ms
1	0	10 ms	20 ms
1	1	15 ms	30 ms

After the last directional step an additional 15 milliseconds of head settling time takes place if the Verify flag is set in Type I commands. Note that this time doubles to 30 ms for

a 1 MHz clock. There is also a 15 ms head settling time if the E flag is set in any Type II or III command.

When a Seek, Step or Restore command is executed an optional verification of Read-Write head position can be performed by setting bit 2 ($V = 1$) in the command word to a logic 1. The verification operation begins at the end of the 15 millisecond settling time after the head is loaded against the media. The track number from the first encountered ID Field is compared against the contents of the Track Register. If the track numbers compare and the ID Field Cyclic Redundancy Check (CRC) is correct, the verify operation is complete and an INTRQ is generated with no errors. If there is a match but not a valid CRC, the CRC error status bit is set (Status bit 3), and the next encountered ID field is read from the disk for the verification operation.

The WD279X must find an ID field with correct track number and correct CRC within 5 revolutions of the media; otherwise the seek error is set and an INTRQ is generated. If $V = 0$, no verification is performed.

The Head Load (HLD) output controls the movement of the read/write head against the media. HLD is activated at the beginning of a Type I command if the h flag is set ($h = 1$), at the end of the Type I command if the verify flag ($V = 1$), or upon receipt of any Type II or III command. Once HLD is active it remains active until either a Type I command is received with ($h = 0$ and $V = 0$); or if the 279X is in an idle state (non-busy) and 15 index pulses have occurred.

Head Load timing (HLT) is an input to the 279X which is used for the head engage time. When $HLT = 1$, the 279X assumes the head is completely engaged. The head engage time is typically 30 to 100 ms depending on drive. The low to high transition on HLT is typically used to fire a one shot. The output of the one shot is then used for HLT and supplied as an input to the 279X.

HEAD LOAD TIMING

When both HLD and HLT are true, the 279X will then read from or write to the media. The "and" of HLD and HLT appears as status Bit 5 in Type I status.

In summary for the Type I commands: if $h = 0$ and $V = 0$, HLD is reset. If $h = 1$ and $V = 0$, HLD is set at the beginning of the command and HLT is not sampled nor is there an internal 15 ms delay. If $h = 0$ and $V = 1$, HLD is set near the end of the command, an internal 15 ms occurs, and the 279X waits for HLT to be true. If $h = 1$ and $V = 1$, HLD is set at the beginning of the command. Near the end of the command, after all the steps have been issued, an internal 15 ms delay occurs and the 279X then waits for HLT to occur.

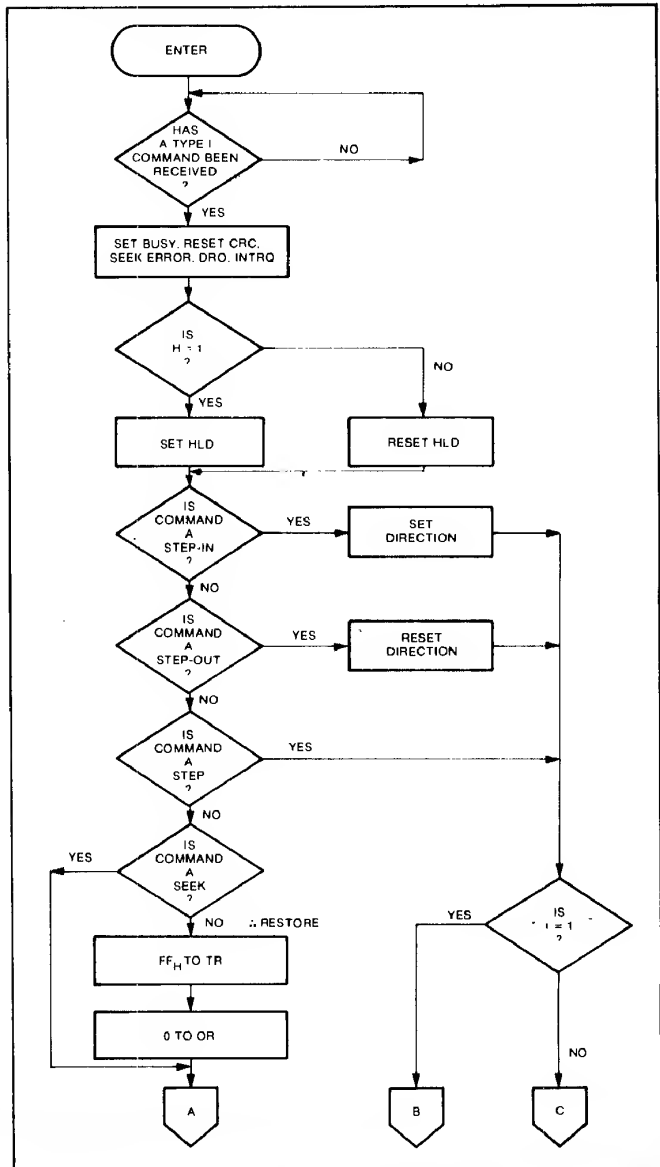

For Type II and III commands with E flag off, HLD is made active and HLT is sampled until true. With E flag on, HLD is made active, an internal 15 ms delay occurs and then HLT is sampled until true.

RESTORE (SEEK TRACK 0)

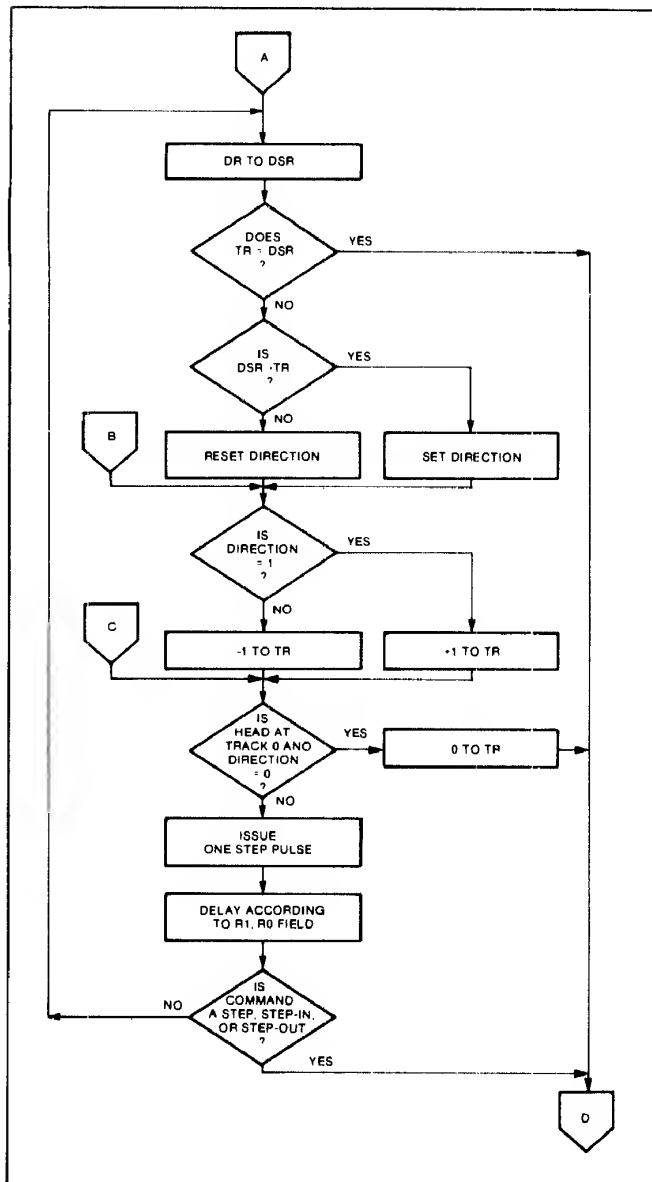

Upon receipt of this command the Track 00 ($\overline{TR00}$) input is sampled. If $\overline{TR00}$ is active low indicating the Read-Write head is positioned over track 0, the Track Register is loaded with zeroes and an interrupt is generated. If $\overline{TR00}$ is not active low, stepping pulses (pins 15 to 16) at a rate specified by the $r1r0$ field are issued until the $\overline{TR00}$ input is activated. At this time the Track Register is loaded with zeroes and an interrupt is generated. If the $\overline{TR00}$ input does not go active low after 255 stepping pulses, the 279X terminates operation, interrupts, and sets the Seek error status bit. A verification operation takes place if the V flag is set. The h bit allows the head to be loaded at the start of command. Note that the Restore command is executed when \overline{MR} goes from an active to an inactive state.

SEEK

This command assumes that the Track Register contains the track number of the current position of the Read-Write head and the Data Register contains the desired track number. The WD279X will update the Track register and issue stepping pulses in the appropriate direction until the

TYPE I COMMAND FLOW

TYPE I COMMAND FLOW

contents of the Track register are equal to the contents of the Data Register (the desired track location). A verification operation takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command. Note: When using multiple drives, the track register must be updated for the drive selected before seeks are issued.

STEP

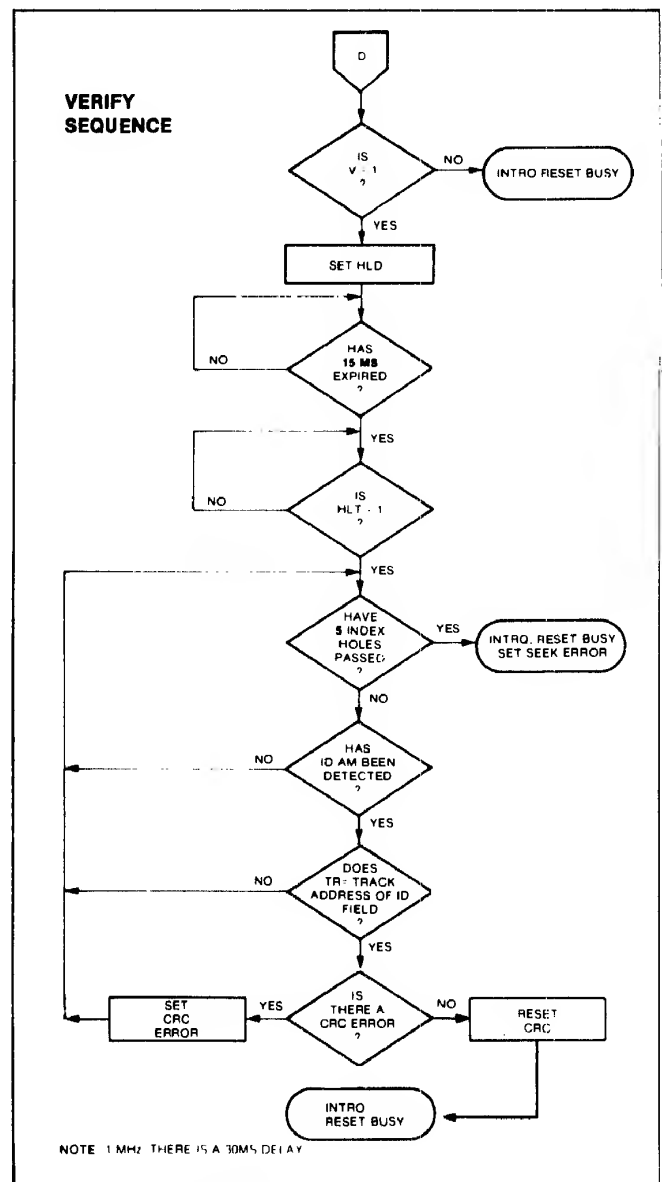

Upon receipt of this command, the 279X issues one stepping pulse to the disk drive. The stepping motor direction is the same as in the previous step command. After a delay determined by the r1r0 field, a verification takes place if the V flag is on. If the T flag is on, the Track Register is updated. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP-IN

Upon receipt of this command, the 279X issues one stepping pulse in the direction towards track 76. If the T flag is on, the Track Register is incremented by one. After a

VERIFY SEQUENCE

NOTE: 1 MHz THERE IS A 30MS DELAY

TYPE I COMMAND FLOW

delay determined by the r1r0 field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

STEP-OUT

Upon receipt of this command, the 279X issues one stepping pulse in the direction towards track 0. If the T flag is on, the Track Register is decremented by one. After a delay determined by the r1r0 field, a verification takes place if the V flag is on. The h bit allows the head to be loaded at the start of the command. An interrupt is generated at the completion of the command.

EXCEPTIONS

On the 2795/7 devices, the SSO output is not affected during Type I commands, and an internal side compare does not take place when the (V) Verify Flag is on.

TYPE II COMMANDS

The Type II Commands are the Read Sector and Write Sector commands. Prior to loading the Type II Command into the Command Register, the computer must load the

that character is lost and the Lost Data Status bit is set. This sequence continues until the complete data field has been inputted to the computer. If there is a CRC error at the end of the data field, the CRC error status bit is set, and the command is terminated (even if it is a multiple sector command).

At the end of the Read operation, the type of Data Address Mark encountered in the data field is recorded in the Status Register (Bit 5) as shown:

**STATUS
BIT 5**

1	Deleted Data Mark
0	Data Mark

WRITE SECTOR

Upon receipt of the Write Sector command, the head is loaded (HLD active) and the Busy status bit is set. When an ID field is encountered that has the correct track number, correct sector number, correct side number, and correct CRC, a DRQ is generated. The 279X counts off 11 bytes in single density and 22 bytes in double density from the CRC field and the Write Gate (WG) output is made active if the DRQ is serviced (i.e., the DR has been loaded by the computer). If DRQ has not been serviced, the command is terminated and the Lost Data status bit is set. If the DRQ has been serviced, the WG is made active and six bytes of zeroes in single density and 12 bytes in double density are then written on the disk. At this time the Data Address Mark is then written on the disk as determined by the a_0 field of the command as shown below:

a_0 Data Address Mark (Bit 0)

1	Deleted Data Mark
0	Data Mark

The 279X then writes the data field and generates DRQ's to the computer. If the DRQ is not serviced in time for continuous writing the Lost Data Status Bit is set and a byte of zeroes is written on the disk. The command is not terminated. After the last data byte has been written on the disk, the two-byte CRC is computed internally and written on the disk followed by one byte of FE in FM or in MFM. The WG output is then deactivated. For a 2 MHz clock the INTRQ will set 8 to 12 μ sec after the last CRC byte is written. For partial sector writing, the proper method is to write the data and fill the balance with zeroes. By letting the chip fill the zeroes, errors may be masked by the lost data status and improper CRC Bytes.

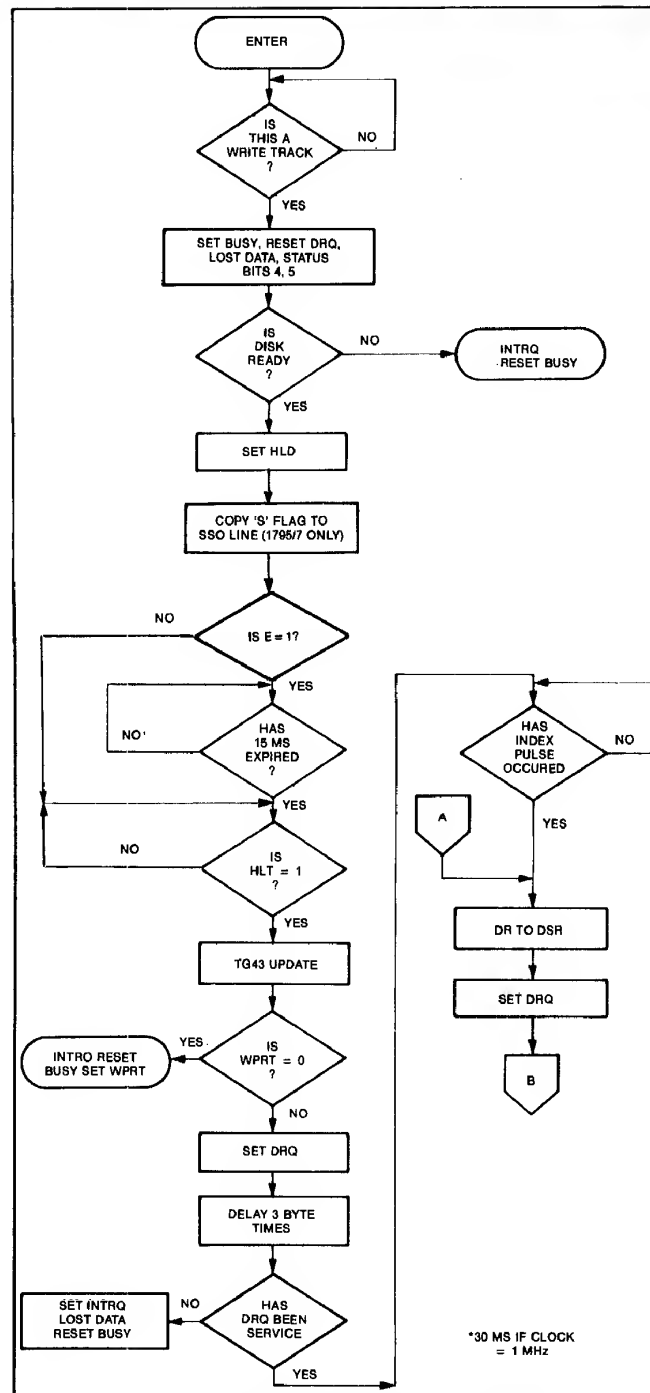

TYPES III COMMANDS

READ ADDRESS

Upon receipt of the Read Address command, the head is loaded and the Busy Status Bit is set. The next encountered ID field is then read in from the disk, and the six data bytes of the ID field are assembled and transferred to the DR, and a DRQ is generated for each byte. The six bytes of the ID field are shown below:

TRACK ADDR	SIDE NUMBER	SECTOR ADDRESS	SECTOR LENGTH	CRC 1	CRC 2
1	2	3	4	5	6

Although the CRC characters are transferred to the

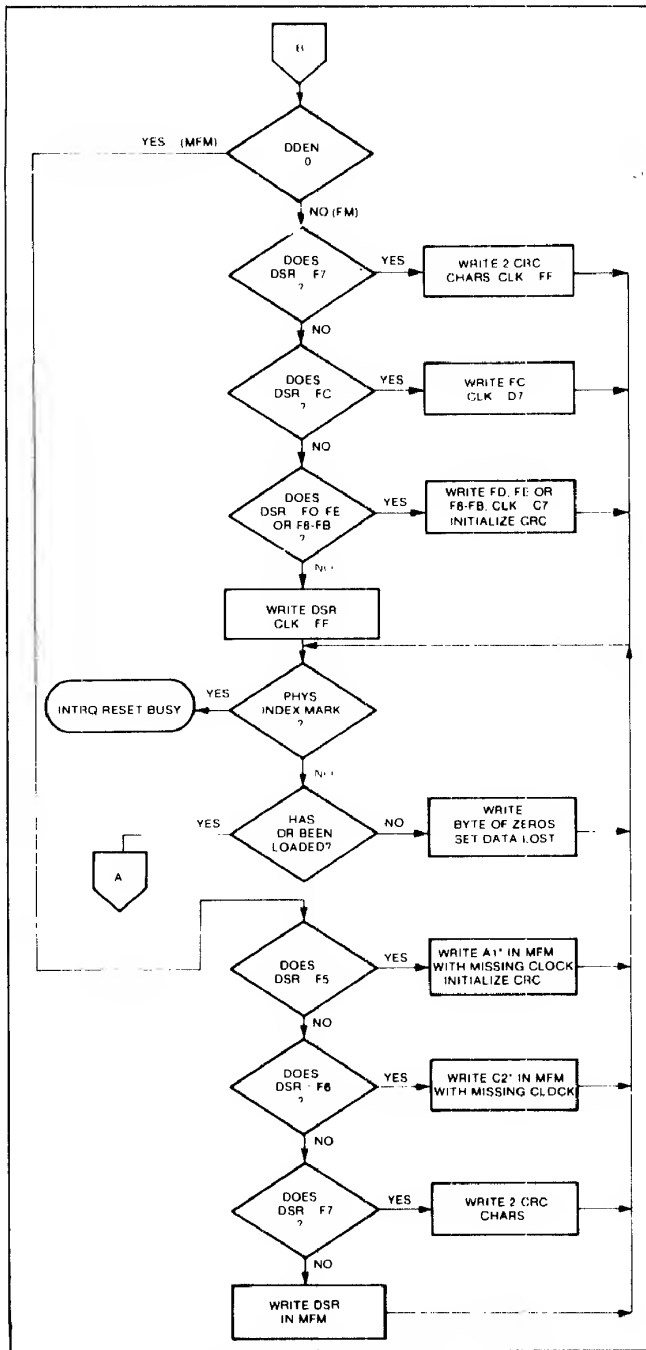

TYPE III COMMAND WRITE TRACK

computer, the 279X checks for validity and the CRC error status bit is set if there is a CRC error. The Track Address of the ID field is written into the sector register so that a comparison can be made by the host. At the end of the operation an interrupt is generated and the Busy Status is reset.

READ TRACK

Upon receipt of the READ track command, the head is loaded, and the Busy Status bit is set. Reading starts with the leading edge of the first encountered index pulse and continues until the next index pulse. All Gap, Header, and data bytes are assembled and transferred to the data register and DRQ's are generated for each byte. The ac-

TYPE III COMMAND WRITE TRACK

accumulation of bytes is synchronized to each address mark encountered. An interrupt is generated at the completion of the command.

This command has several characteristics which make it suitable for diagnostic purposes. They are: no CRC checking is performed; gap information is included in the data stream; the internal side compare is not performed; and the address mark detector is on for the duration of the command. Because the A.M. detector is always on, write splices or noise may cause the chip to look for an A.M. If an address mark does not appear on schedule with the Lost Data status flag being set.

The ID A.M., ID field, ID CRC bytes, DAM, Data and Data CRC Bytes for each sector will be correct. The Gap Bytes may be read incorrectly during write-splice time because of synchronization.

WRITE TRACK FORMATTING THE DISK

(Refer to section on Type III commands for flow diagrams.)

Formatting the disk is a relatively simple task when operating programmed I/O or when operating under DMA with a large amount of memory. Data and gap information must be provided at the computer interface. Formatting the disk is accomplished by positioning the R/W head over the desired track number and issuing the Write Track command.

Upon receipt of the Write Track command, the head is loaded and the Busy Status bit is set. Writing starts with the leading edge of the first encountered index pulse and continues until the next index pulse, at which time the interrupt is activated. The Data Request is activated immediately upon receiving the command, but writing will not start until after the first byte has been loaded into the Data Register. If the DR has not been loaded by the time the index pulse is encountered the operation is terminated making the device Not Busy, the Lost Data Status Bit is set, and the interrupt is activated. If a byte is not present in the DR when needed, a byte of zeroes is substituted.

This sequence continues from one index mark to the next index mark. Normally, whatever data pattern appears in the data register is written on the disk with a normal clock pattern. However, if the 279X detects a data pattern of F5 thru FE in the data register, this is interpreted as data address marks with missing clocks or CRC generation.

The CRC generator is initialized when any data byte from F8 to FE is about to be transferred from the DR to the DSR

CONTROL BYTES FOR INITIALIZATION

DATA PATTERN IN DR (HEX)	WD279X INTERPRETATION IN FM (DDEN = 1)	WD279X INTERPRETATION IN MFM (DDEN = 0)
00 thru F4	Write 00 thru F4 with CLK = FF	Write 00 thru F4, in MFM
F5	Not Allowed	Write A1* in MFM, Preset CRC
F6	Not Allowed	Write C2** in MFM
F7	Generate 2 CRC bytes	Generate 2 CRC bytes
F8 thru FB	Write F8 thru FB, Clk = C7, Preset CRC	Write F8 thru FB, in MFM
FC	Write FC with Clk = D7	Write FC in MFM
FD	Write FD with Clk = FF	Write FD in MFM
FE	Write FE, Clk = C7, Preset CRC	Write FE in MFM
FF	Write FF with Clk = FF	Write FF in MFM

* Missing clock transition between bits 4 and 5

** Missing clock transition between bits 3 and 4

or by receipt of F5 in MFM. An F7 pattern will generate two CRC characters in FM or MFM. As a consequence, the patterns F5 thru FE must not appear in the gaps, data fields, or ID fields. Also, CRC's must be generated by an F7 pattern.

Disks may be formatted in IBM 3740 or System 34 formats with sector lengths of 128, 256, 512, or 1024 bytes.

TYPE IV COMMANDS

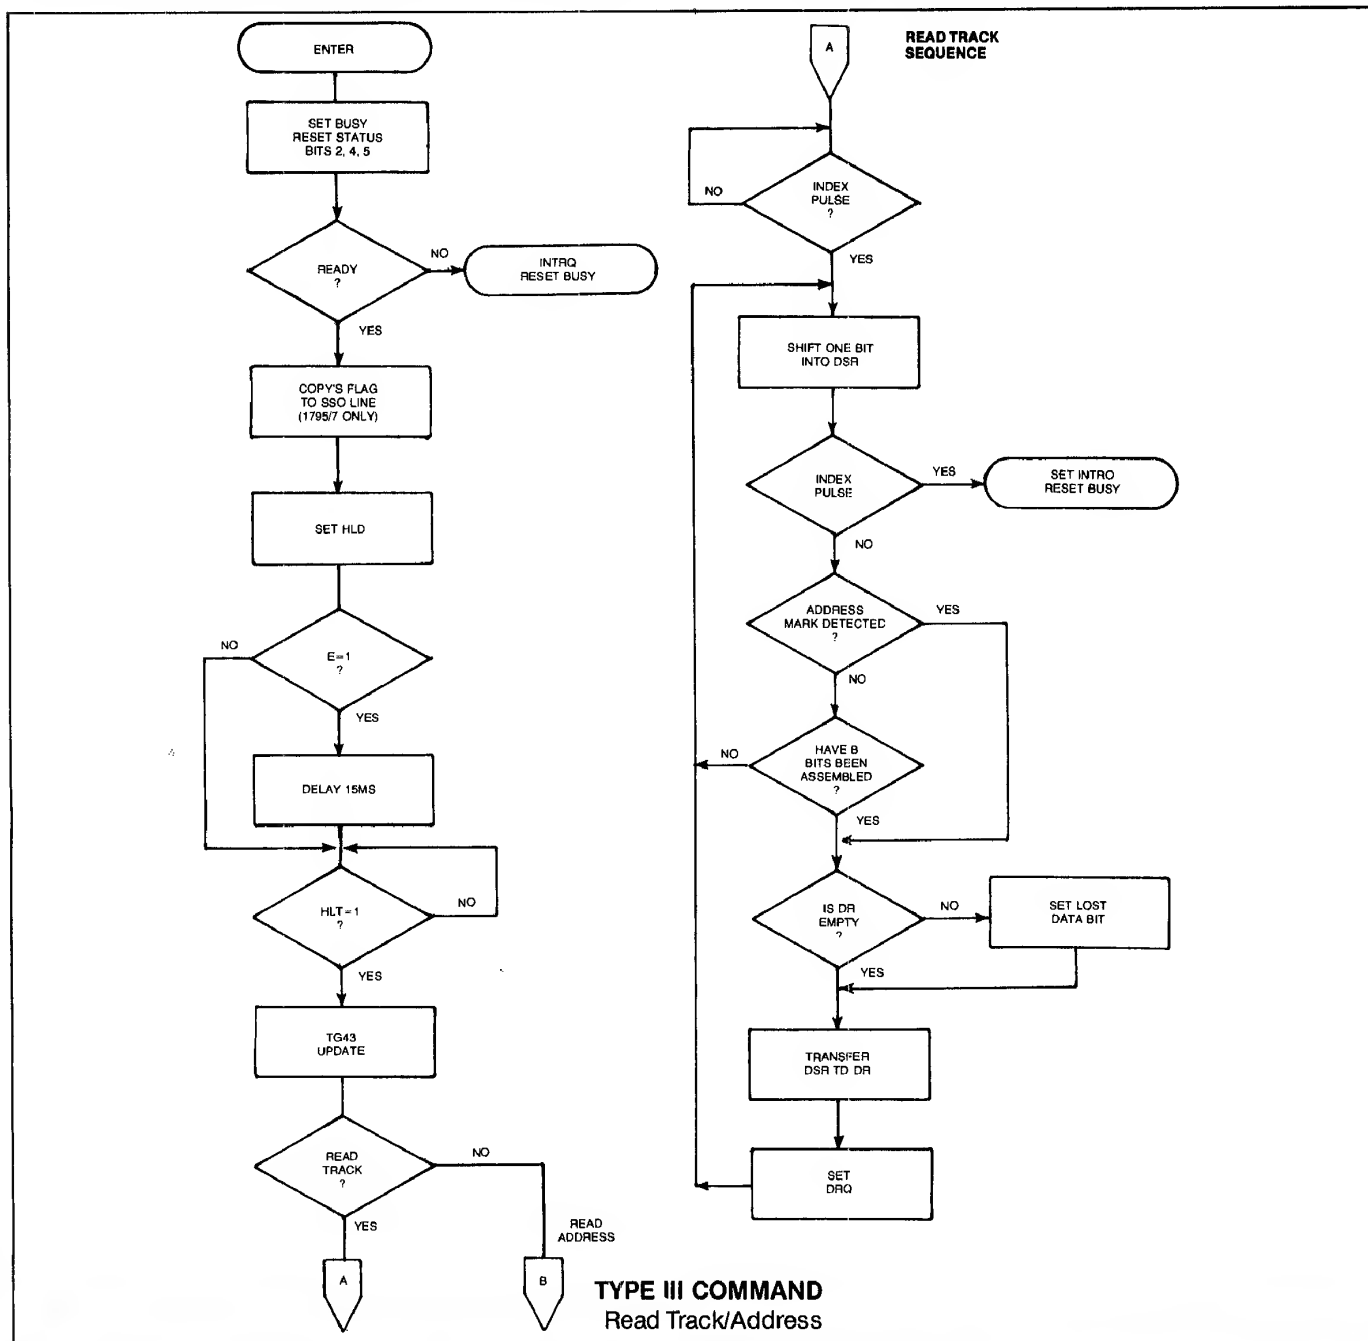

The Forced Interrupt command is generally used to terminate a multiple sector read or write command or to insure Type I status in the status register. This command can be loaded into the command register at any time. If there is a current command under execution (busy status bit set) the command will be terminated and the busy status bit

reset.

The lower four bits of the command determine the conditional interrupt as follows:

- I0 = Not-Ready to Ready Transition
- I1 = Ready to Not-Ready Transition
- I2 = Every Index Pulse
- I3 = Immediate Interrupt

The conditional interrupt is enabled when the corresponding bit positions of the command (I3 - I0) are set to a 1. Then, when the condition for interrupt is met, the INTRQ line will go high signifying that the condition specified has occurred. If I3 - I0 are all set to zero (HEX D0), no interrupt will occur but any command presently under execution will be immediately terminated. When using the immediate

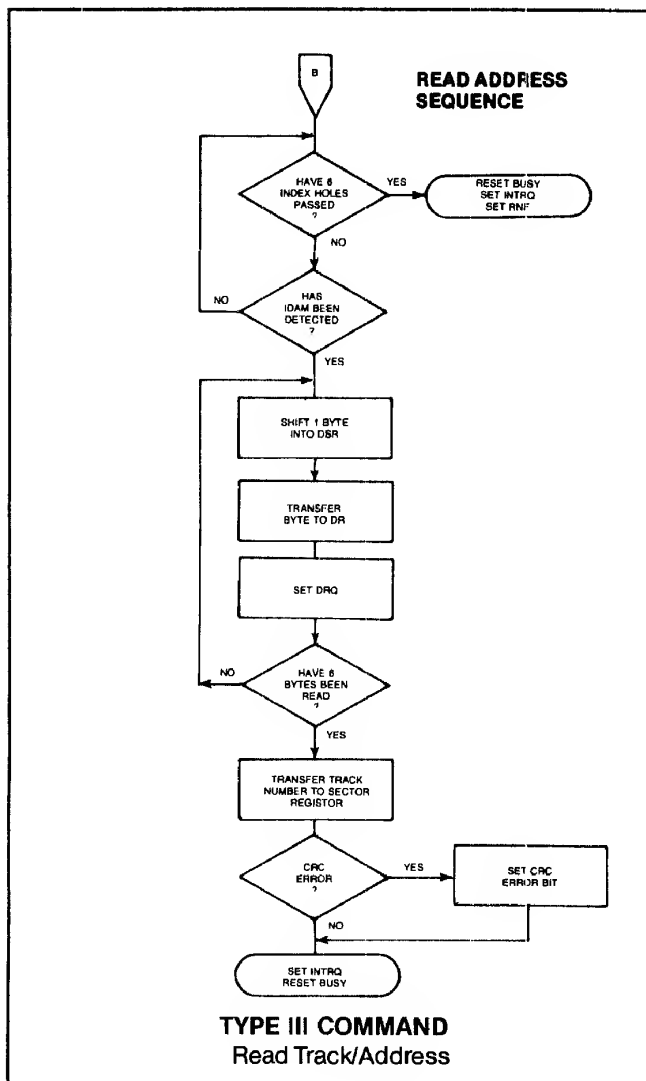

interrupt condition ($I_3 = 1$), an interrupt will be immediately generated and the current command terminated. Reading the status or writing to the command register will not automatically clear the interrupt. The HEX D0 is the only command that will enable the immediate interrupt (HEX D8) to clear on a subsequent load command register or read status register operation. Follow a HEX D8 with D0 command.

Wait 8 micro sec (double density) or 16 micro sec (single density) before issuing a new command after issuing a forced interrupt (times double when clock = 1 MHz). Loading a new command sooner than this will nullify the forced interrupt.

Forced interrupt stops any command at the end of an internal micro-instruction and generates INTRQ when the specified condition is met. Forced interrupt will wait until ALU operations in progress are complete (CRC calculations, compares, etc.)

More than one condition may be set at a time. If for example, the READY TO NOT-READY condition ($I_1 = 1$) and the Every Index Pulse ($I_2 = 1$) are both set, the resultant command would be HEX "DA." The "OR" function is performed so that either a READY TO NOT-READY or the next Index Pulse will cause an interrupt condition.

STATUS REGISTER

Upon receipt of any command, except the Force Interrupt command, the Busy Status bit is set and the rest of the status bits are updated or cleared for the new command. If the Force Interrupt Command is received when there is a current command under execution, the Busy status bit is reset, and the rest of the status bits are unchanged. If the Force Interrupt command is received when there is not a current command under execution, the Busy Status bit is reset and the rest of the status bits are updated or cleared. In this case, Status reflects the Type I commands.

The user has the option of reading the status register through program control or using the DRQ line with DMA or interrupt methods. When the Data register is read the DRQ bit in the status register and the DRQ line are automatically reset. A write to the Data register also causes both DRQ's to reset.

The busy bit in the status may be monitored with a user program to determine when a command is complete, in lieu of using the INTRQ line. When using the INTRQ, a busy status check is not recommended because a read of the status register to determine the condition of busy will reset the INTRQ line.

The format of the Status Register is shown below:

(BITS)							
7	6	5	4	3	2	1	0
S7	S6	S5	S4	S3	S2	S1	S0

Status varies according to the type of command executed as shown in Table 4.

Because of internal sync cycles, certain time delays must be observed when operating under programmed I/O. They are: (times double when clock = 1 MHz)

Operation	Next Operation	Delay Req'd.	
		FM	MFM
Write to Command Reg.	Read Busy Bit (Status Bit 0)	12 μ s	6 μ s
Write to Command Reg.	Read Status Bits 1-7	28 μ s	14 μ s
Write Any Register	Read From Diff. Register	0	0

IBM 3740 FORMAT — 128 BYTES/SECTOR

Shown below is the IBM single-density format with 128 bytes/sector. In order to format a diskette, the user must issue the Write Track command, and load the data register with the following values. For every byte to be written, there is one Data Request.

NUMBER OF BYTES	HEX VALUE OF BYTE WRITTEN
40	FF (or 00) ³
6	00
1	FC (Index Mark)
1	FF (or 00)
6	00
1	FE (ID Address Mark)
1	Track Number
1	Side Number (00 or 01)
1	Sector Number (1 thru 1A)
1	00 (Sector Length)
1	F7 (2 CRC's written)
11	FF (or 00)
6	00
1	FB (Data Address Mark)
128	Data (IBM uses E5)
1	F7 (2 CRC's written)
27	FF (or 00)
247	FF (or 00)

1. Write bracketed field 26 times
2. Continue writing until 279X interrupts out.
Approx. 247 bytes.
3. A '00' option is allowed on 2795/7 only.

IBM SYSTEM 34 FORMAT- 256 BYTES/SECTOR

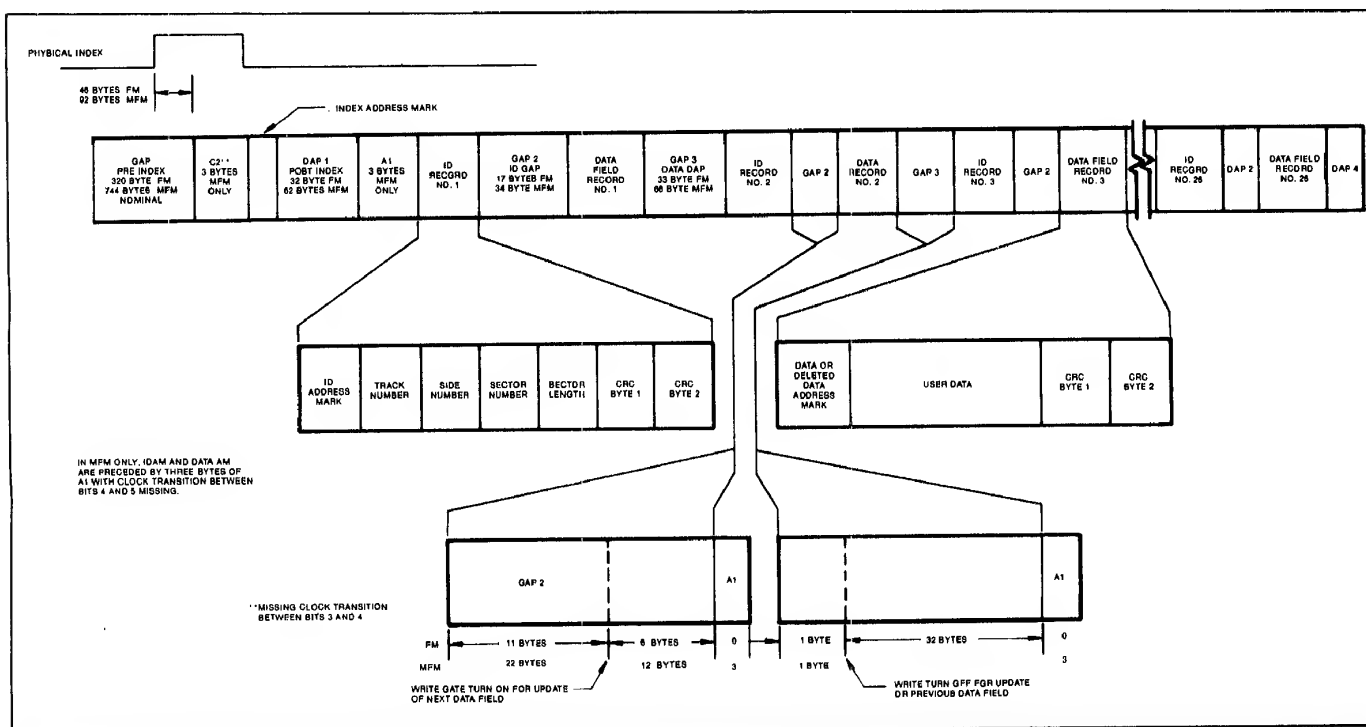

Shown below is the IBM dual-density format with 256 bytes/sector. In order for format a diskette the user must

issue the Write Track command and load the data register with the following values. For every byte to be written, there is one data request.

NUMBER OF BYTES	HEX VALUE OF BYTE WRITTEN
80	4E
12	00
3	F6 (Writes C2)
1	FC (Index Mark)
1	4E
12	00
3	F5 (Writes A1)
1	FE (ID Address Mark)
1	Track Number (0 thru 4C)
1	Side Number (0 or 1)
1	Sector Number (1 thru 1A)
1	01 (Sector Length)
1	F7 (2 CRCs written)
22	4E
12	00
3	F5 (Writes A1)
1	FB (Data Address Mark)
256	DATA
1	F7 (2 CRCs written)
54	4E
598*	4E

* Write bracketed field 26 times

** Continue writing until 279X interrupts out.
Approx. 598 bytes.

IBM TRACK FORMAT

1. NON-IBM FORMATS

Variations in the IBM formats are possible to a limited extent if the following requirements are met:

- 1) Sector size must be 128, 256, 512 or 1024 bytes.
- 2) Gap 2 cannot be varied from the IBM format.
- 3) 3 bytes of A1 must be used in MFM.

In addition, the Index Address Mark is not required for operation by the 279X. Gap 1, 3, and 4 lengths can be as short as 2 bytes for 279X operation, however PLL lock up time, motor speed variation, write splice area, etc. will add more bytes to each gap to achieve proper operation. It is recommended that the IBM format be used for highest system reliability.

	FM	MFM
Gap I	16 bytes FF	32 bytes 4E
Gap II	11 bytes FF	22 bytes 4E
*	6 bytes 00	12 bytes 00
*		3 bytes A1
Gap III**	10 bytes FF 4 bytes 00	24 bytes 4E 8 bytes 00 3 bytes A1
Gap IV	16 bytes FF	16 bytes 4E

* Byte counts must be exact.

** Byte counts are minimum, except exactly 3 bytes of A1 must be written.

ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings

Voltage to any input with respect to $V_{SS} = +15$ to $-0.3V$

C_{IN} & $C_{OUT} = 15$ pF max with all pins grounded except one under test.

WD1691 Floppy Support Logic (F.S.L.)

WD1691

FEATURES

- DIRECT INTERFACE TO THE FD179X
- ELIMINATES EXTERNAL FDC LOGIC
- DATA SEPARATION/RCLK GENERATION
- WRITE PRECOMPENSATION SIGNALS
- VFOE/WF DEMULTIPLEXING
- PROGRAMMABLE DENSITY
- 8" OR 5.25" DRIVE COMPATIBLE
- ALL INPUTS AND OUTPUTS TTL COMPATIBLE
- SINGLE +5V SUPPLY

GENERAL DESCRIPTION

The WD1691 F.S.L. has been designed to minimize the external logic required to interface the 179X Family of Floppy Disk Controllers to a drive. With the use of an external VCO, the WD 1691 will generate the RCLK signal for the WD179X, while providing an adjustment pulse (PUMP) to control the VCO frequency. VFOE/WF de-multiplexing is also accomplished and Write Precompensation signals have been included to interface directly with the WD2143 Clock Generator.

The WD1691 is implemented in N-MOS silicon gate technology and is available in a plastic or ceramic 20 pin dual-in-line package.

Figure 1 WD1691 PIN CONNECTIONS

Figure 2 WD1691 BLOCK DIAGRAM

PIN	NAME	SYMBOL	FUNCTION
1	WRITE DATA INPUT	WDIN	Ties directly to the FD179X WD pin.
2, 3, 4, 19	PHASE 2, 3, 1, 4	$\overline{\phi 2} \ \overline{\phi 3} \ \overline{\phi 1} \ \overline{\phi 4}$	4 Phase inputs to generate a desired Write Precompensation delay. These signals tie directly to the WD2143 Clock Generator.
5	STROBE	STB	Strobe output from the 1691. Strobe will latch at a high level on the leading edge of WDIN and reset to a low level on the leading edge of $\phi 4$.
6	WRITE DATA OUTPUT	WDOUT	Serial, pre-compensated Write data stream to be sent to the disk drive's WD line.
7	WRITE GATE	WG	Ties directly to the FD179X WG pin.
8	VFO ENABLE/ WRITE FAULT	$\overline{\text{VFOE/WF}}$	Ties directly to the FD179X $\overline{\text{VFOE/WF}}$ pin.
9	TRACK 43	TG43	Ties directly to the FD179X TG43 pin. If Write Precompensation is required on TRACKS 44-76.
10	V _{SS}	V _{SS}	Ground
11	READ DATA	$\overline{\text{RDD}}$	Composite clock and data stream input from the drive.
12	READ CLOCK	RCLK	RCLK signal generated by the WD1691, to be tied to the FD179X RCLK pin.
13	PUMP UP	PU	Tri-state output that will be forced high when the WD1691 requires an increase in VCO frequency.
14	PUMP DOWN	$\overline{\text{PD}}$	Tri-state output that will be forced low when the WD1691 required a decrease in VCO frequency.
15	Double Density Enable	$\overline{\text{DDEN}}$	Double Density Select input. When Inactive (High), the VCO frequency is internally divided by two.
16	Voltage Controlled Oscillator	VCO	A nominal 4.0MHz (8" drive) or 2.0MHz (5.25" drive) master clock input.
17, 18	EARLY LATE	EARLY LATE	EARLY and LATE signals from the FD179X, used to determine Write Precompensation.

Figure 4 DATA RECOVERY LOGIC

DEVICE DESCRIPTION

The WD1691 is divided into two sections:

- 1) Data Recovery Circuit
- 2) Write precompensation Circuit

The Data Separator or Recovery Circuit has four inputs: DDEN, VCO, RDD, and VFOE/WF; and three outputs: PU, PD and RCLK. The VFOE/WF input is used in conjunction with the Write Gate signal to enable the Data recovery circuit. When Write Gate is high, a write operation is taking place, and the data recovery circuits are disabled, regardless of the state on any other inputs.

The Write Precompensation circuit has been designed to be used with the WD2143-03 clock generator. When the WD1691 is operated in a "single density only" mode, write precompensation as well as the WD2143-03 is not needed. In this case, $\phi 1$, $\phi 2$, $\phi 3$, $\phi 4$, and STB should be tied together, DDEN left open, and TG43, WDIN, Early, and Late tied to ground.

In the double-density mode ($\overline{\text{DDEN}}=0$), the signals Early and Late are used to select a phase input ($\phi 1 - \phi 4$) on the leading edge of WDIN. The STB line is latched high when this occurs, causing the WD2143-03 to start its pulse generation. $\phi 2$ is used as the write data pulse on nominal ($\text{Early}=\text{Late}=\phi$), $\phi 1$ is used for early, and $\phi 3$ is used for late. The leading edge of $\phi 4$ resets the STB line in anticipation of the next write data pulse. When TG43=0 or $\overline{\text{DDEN}}=1$, Precompensation is disabled and any transitions on the WDIN line will appear on the WData line. If write precompensation is desired on all tracks, leave TG43 open (an internal pull-up will force a Logic 1) while $\overline{\text{DDEN}}=0$.

The signals, DDEN, TG43, and RDD have internal pull-up resistors and may be left open if a logic 1 is desired on any of these lines.

When VFOE/WF and WRITE GATE are low, the data recovery circuit is enabled. When the RDD line goes Active

Low, the PU or PD signals will become active. See Figure 4. If the RDD line has made its transition in the beginning of the RCLK window, PU will go from a HI-Z state to a Logic 1, requesting an *increase* in VCO frequency. If the RDD line has made its transition at the end of the RCLK window, PU will remain in a HI-Z state while PD will go to a logic zero, requesting a *decrease* in VCO frequency. When the leading edge of RDD occurs in the center of the RCLK window, both PU and PD will remain tri-stated, indicating that no adjustment of the VCO frequency is needed. See Figure 3. The RCLK signal is a divide-by-16 ($\overline{\text{DDEN}}=1$) or a divide-by-8 ($\overline{\text{DDEN}}=0$) of the VCO frequency.

The minimum Voh level on PU is specified at 2.4V, sourcing 200ua. During PUMP UP time, this output will go from a tri-state to .4V minimum. By tying PU and PD together, a PUMP signal is created that will be forced low for a decrease in VCO frequency and forced high for an increase in VCO frequency. To speed up rise times and stabilize the output voltage, a resistor divider can be used to set the tristate level to approximately 1.4V. This yields a worst case swing of $\pm 1V$; acceptable for most VCO chips with a linear voltage-to-frequency characteristic.

Both PU and PD signals are affected by the width of the RAW READ (RDD) pulse. The wider the RAW READ pulse, the longer the PU or PD signal (depending upon the phase relationship to RCLK) will remain active. If the RAW READ pulse exceeds 250ns, ($\text{VCO} = 4\text{MHz}$, $\overline{\text{DDEN}} = 0$) or 500ns. ($\text{VCO} = 2\text{MHz}$, $\overline{\text{DDEN}} = 1$), then both a PU and PD will occur in the same window. This is undesirable and reduces the accuracy of the external integrator or low-pass filter to convert the PUMP signals into a slow moving D.C. correction voltage.

Eventually, the PUMP signals will have corrected the VCO input to exactly the same frequency multiple as the RAW READ signal. The leading edge of the RAW READ pulse will then occur in the exact center of the RCLK window, an ideal condition for the FD179X internal recovery circuits.

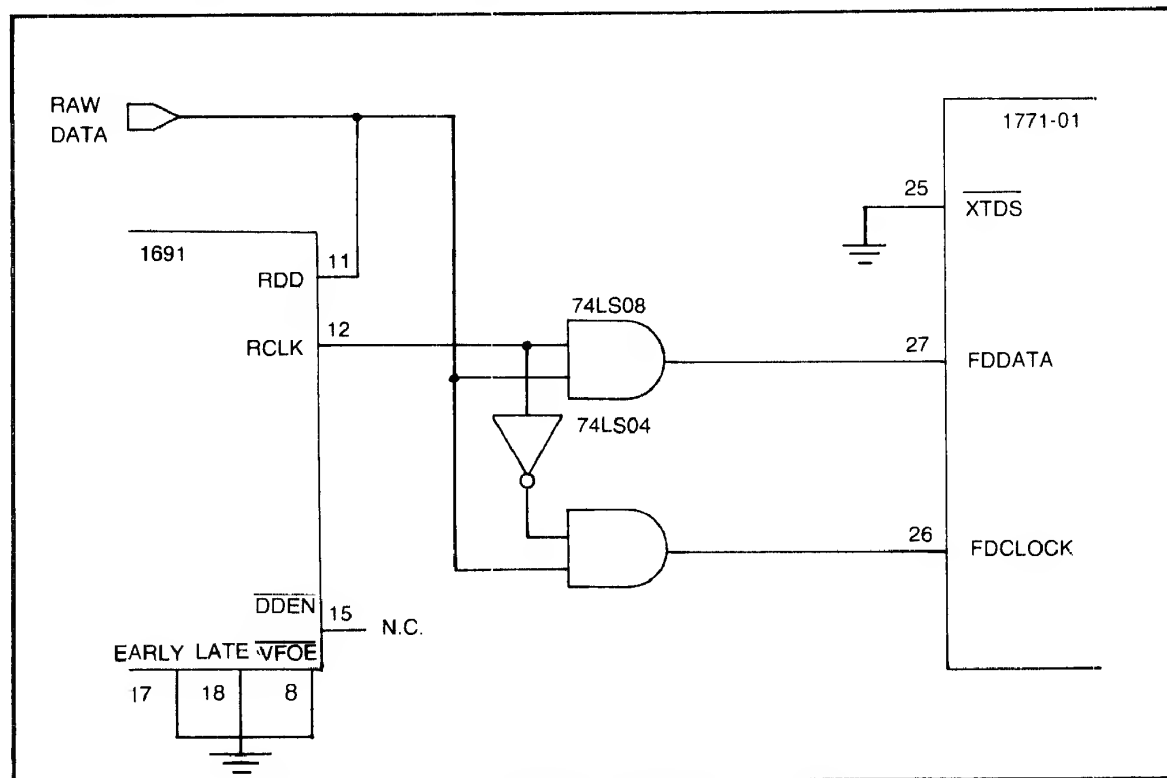

Figure 9 WD1691 to FD1771-01 INTERFACE

TYPICAL APPLICATIONS

Figure 9 illustrates the 1691 to FD1771-01 floppy disk controller. The RCLK signal is used to gate the RAW data pulses which are inverted by the 74LS04 inverter. Since RCLK will be high during data and low during clock a 74LS08 is used to switch the proper clock or data pulse to the FD1771.

Shown in Figure 10 is a Phase-Lock Loop data separator and the support logic for a single and double-density 8" drive. The raw data (Both clock and data bits) are fed to the WD1691 and FD179X. The WD1691 outputs its PU or PD signal, which is integrated by the .33uf capacitor and 33ohm resistor to form a control voltage for the 74S124 VCO device. The 4.0MHZ nominal output of the VCO then feeds back to the WD1691 completing the loop. The WD2143-03 is also used, providing write precompensation when in double-density, from tracks 44-77. The DDEN line can either be controlled by a toggle switch or a logic level from the host system.

ALIGNMENT

To adjust write precompensation, issue a command to the FD179X so that write data pulses are present. This can be done with a 'WRITE TRACK' command and the IP line open, or a continuous 'WRITE SECTOR' operation. With a scope on pin 4 of the WD1691, adjust the precomp pot for the desired value. This will range from 100 to 300 ns typically.

The pulse width set on pin 4 (Ø1) will be the desired pre-comp delay from nominal.

The data separator must be adjusted with the RDD or VFOE/WF line at a Logic 1. Adjust the bias voltage poten-

tiometer for 1.4V on pin 2 of the 74S124. Then adjust the range control to yield 4.0MHZ on pin 7 of the 74S124.

SUBSTITUTING VCO's

There are other VCO circuits available that may be substituted for the 74S124. The specifications required are:

- 1) The VCO must free run at 4.0MHZ with a 1.4V control signal. The WD1691 will force this voltage 1 Volt in either direction (i.e., .4V = decrease frequency, 2.4V = increase frequency). If a $\pm 15\%$ capture range is desired, then a 1 Volt change on the VCO input should change the frequency by 15%. Capture range should be limited to about $\pm 25\%$, to prevent the VCO from breaking into oscillation and/or losing lock because of noise spikes (causing abnormally quick adjustments of the VCO frequency). Jitter in the VCO output frequency may further be reduced by increasing the integration capacitor/resistor, but this will also decrease the final capture range and lock-up time.
- 2) The sink output current of the WD1691 is 3.2ma minimum. The source output current is $-200\mu\text{a}$. Therefore, source current is the limiting factor. Insure that the input circuitry of the VCO does not require source current in excess of $-200\mu\text{a}$.

Another alternative is to use a voltage follower/level shifter circuit to match the input requirements of the VCO chosen. A more complex filter can be used to convert the PUMP UP/PUMP DOWN pulses to the varying DC voltage signal required by the VCO, achieving an optimum condition between lock-up time and high frequency rejection.

DM1883A/B Direct Memory Access Controller

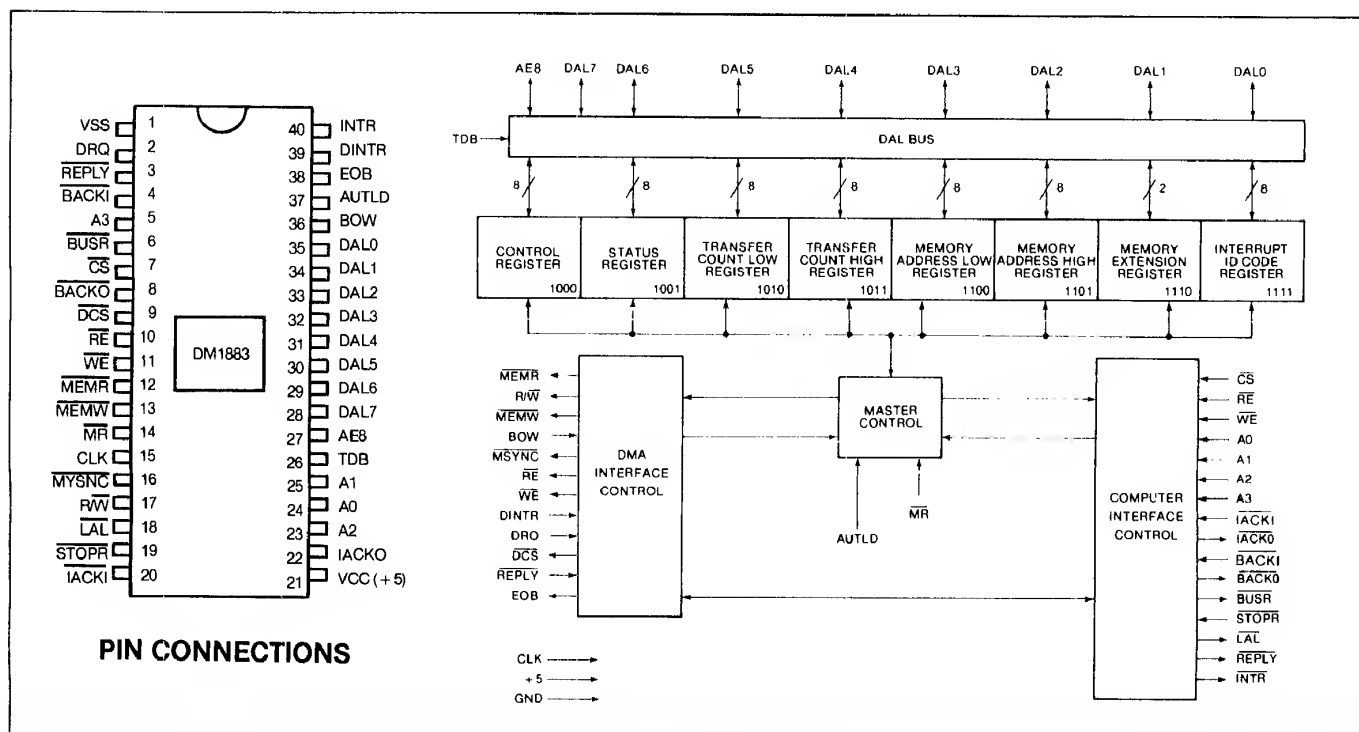

DM1883A/B

FEATURES

- AUTOMATIC DAISY CHAINING OF BUS AND INTERRUPT ACKNOWLEDGE SIGNALS
- AUTO LOAD OPTION
- SINGLE +5 VDC POWER SUPPLY
- 8 BIT BI-DIRECTIONAL DATA BUS
- TRUE OR COMPLEMENT DATA BUS
- 8 CPU ADDRESSABLE DMAC REGISTERS
- 8 CPU ADDRESSABLE DEVICE REGISTERS
- AUTOMATIC GENERATION OF DEVICE CS DURING DMA AND CPU DEVICE ACCESSES
- 256K MEMORY ADDRESSING
- 64K PROGRAMMABLE PAGE PROTECTION
- BYTE OR WORD DMA TRANSFERS
- INTERRUPT AND BUS REQUEST CAPABILITIES
- END-OF-BLOCK SHUT OFF BY DMAC
- TIME-OUT INTERRUPT CAPABILITY
- SINGLE CLOCK INPUT
- CS, RE, WE, A0-A3 ADDRESSING
- STOP REQUEST INPUT TO DELAY INTERRUPT OR BUS REQUESTS
- COMPATIBLE WITH OUR FLOPPY DISC CONTROLLERS
- 8 BIT PROGRAMMABLE INTERRUPT ID CODE

GENERAL DESCRIPTION

The DM1883 Direct Memory Access Controller (DMAC) is packaged in a 40 pin standard dual in-line package. The chip requires a single +5 power supply input and a single clock input. The device contains 8 CPU addressable registers, and allows for up to 8 CPU addressable device registers if the automatic device chip select feature is used. Byte or word transfers can be programmed, and all memory DMA operations are handshaked for compatibility with a variety of bus structures. Up to 256K bytes of memory can be accessed directly with 64K page protection and nonexistent memory interrupt as options. Bus and Interrupt Acknowledge signals are internally daisy chained, and a STOP REQUEST input prevents new requests while a current request is active. Device accesses are not handshaked, and a BUS HOLD feature is present for high speed devices. Device interrupt input, end-of-block output, and I/O read/write output pins simplify hardware interfacing to the device and the CPU bus. The AUTO LOAD feature allows automatic boot-loading of up to 64K bytes or words into memory starting at location zero. An 8 bit interrupt ID code is also provided.

INTERFACE SIGNALS DESCRIPTIONS

PIN NUMBER	SIGNAL NAME	SYMBOL	FUNCTION
1	GROUND	VSS	Ground
2	DATA REQUEST	DRQ	Data service request input from the peripheral device. A DMA transfer is initiated when this signal goes high.
3	$\overline{\text{REPLY}}$	$\overline{\text{REPLY}}$	Active low bi-directional handshake signal for both CPU and DMA transfers.
4	$\overline{\text{BACK IN}}$	$\overline{\text{BACKI}}$	Bus acknowledge in. An active low input signal from the CPU or a previous device in the $\overline{\text{BACK}}$ daisy chain. When low this signal will initiate a DMA transfer if the DMAC was requesting a DMA cycle.
5, 23, 24, 25	REGISTER SELECTS	A0-A3	These inputs select one of eight DMAC registers or one of eight device registers. When A3 is high the DMAC is selected. When A3 is low the DMAC is deselected and $\overline{\text{DCS}}$ is made low by the DMAC to activate device transfers. $\overline{\text{CS}}$ input to the DMAC must be made low before either the DMAC or the device may be selected by the CPU.
6	$\overline{\text{BUS REQUEST}}$	$\overline{\text{BUSR}}$	Active low output signal to initiate a CPU bus request and to latch A8-A15, A17 of the 18 bit DMA transfer address from DAL0-DAL7, AE8 into an external register.
7	$\overline{\text{CHIP SELECT}}$	$\overline{\text{CS}}$	Active low chip select input signal for CPU controlled operations.
8	$\overline{\text{BACK OUT}}$	$\overline{\text{BACKO}}$	Bus acknowledge out. An active low output signal used to pass $\overline{\text{BACKI}}$ along the daisy chain when the DMAC is not requesting a DMA cycle. This output is not affected by $\overline{\text{STOPR}}$.
9	$\overline{\text{DEVICE SELECT}}$	$\overline{\text{DCS}}$	Active low device chip select output signal for CPU and DMAC controlled operations.
10	$\overline{\text{READ ENABLE}}$	$\overline{\text{RE}}$	Active low bi-directional read enable for the DMAC and the device.
11	$\overline{\text{WRITE ENABLE}}$	$\overline{\text{WE}}$	Active low bi-directional write enable for the DMAC and the device. $\overline{\text{RE}}$ and $\overline{\text{WE}}$ are inputs during CPU controlled operations, and outputs to the device during DMAC controlled operations.
12	$\overline{\text{MEMORY READ}}$	$\overline{\text{MEMR}}$	Active low output to initiate a memory read during DMA transfers to the peripheral device.
13	$\overline{\text{MEMORY WRITE}}$	$\overline{\text{MEMW}}$	Active low output to initiate a memory write during DMA transfers from the peripheral device.
14	$\overline{\text{MASTER RESET}}$	$\overline{\text{MR}}$	Active low master reset signal to initialize the DMAC.
15	CLOCK	CLK	Clock input
16	$\overline{\text{MEMORY SYNC}}$	$\overline{\text{MSYNC}}$	Active low memory sync output to initiate a memory access during DMA transfers.
17	$\overline{\text{READ/WRITE}}$	R/ $\overline{\text{W}}$	This output indicates the direction of transfer for the peripheral device. High for device-to-memory transfers (READ), and low for memory to device transfers (WRITE). Tied directly to Control Register bit 4.
18	$\overline{\text{LOAD ADDRESS LOW}}$	$\overline{\text{LAL}}$	Active low output signal to latch A0-A7, A16 of the 18-bit DMA transfer address from DAL0-DAL7, AE8 into an external register. $\overline{\text{BUSR}}$ and $\overline{\text{LAL}}$ are compatible with INTEL 8212 devices.

PIN NUMBER	SIGNAL NAME	SYMBOL	FUNCTION
19	STOP REQUEST	STOPR	Active low input that prevents $\overline{\text{INTR}}$ and $\overline{\text{BUSR}}$ from going low even if a request becomes active. An active $\overline{\text{INTR}}$ or $\overline{\text{BUSR}}$ request will not be affected by this input going low. This signal is used to speed up daisy chaining of bus and interrupt acknowledge inputs, and to prevent new requests while some other request is in the process of being serviced.
20	$\overline{\text{IACK IN}}$	$\overline{\text{IACKI}}$	Interrupt acknowledge in. An active low input signal from the CPU or a previous device in the $\overline{\text{IACK}}$ daisy chain. The DMAC is selected when $\overline{\text{INTR}}$ is low and this signal goes low. If $\overline{\text{RE}}$ also goes low while the DMAC is selected via this signal then the interrupt ID code is gated onto DAL0-DAL7.
21	POWER SUPPLY	V_{CC}	+5 VDC power supply input
22	$\overline{\text{IACK OUT}}$	$\overline{\text{IACKO}}$	Interrupt acknowledge out. An active low output signal used to pass $\overline{\text{IACKI}}$ along the daisy chain when the DMAC is not requesting an interrupt. This output is not affected by $\overline{\text{STOPR}}$.
26	TRUE DATA BUS	TDB	This input selects a true data bus on the DAL lines when high or open, and a complemented data bus on the DAL lines when low.
27	ADDRESS EXTENSION	AE8	Address extension bit output. Used during DMA operations to extend the address to 18 bits. This bit is true if TDB is high and complemented if TDB is low.
28-35	DATA ACCESS LINES	DAL0-DAL7	An 8-bit bi-directional three-state bus for CPU and DMAC controlled transfers to and from the DMAC. These signals remain in a three-state mode if the peripheral device is selected via A3 instead of the DMAC.
36	BYTE OR WORD	BOW	Byte or word DMA transfer mode input. When high memory addresses are incremented by one after every DMA transfer. When low memory addresses are incremented by two after every DMA transfer and the LSB of the memory address is forced to zero.
37	AUTO LOAD	AUTLD	Active high input to initiate a non-programmed 64K device to memory data transfer.
38	END OF BLOCK	EOB	Active high output to shut off the peripheral device when the transfer count goes to zero.
39	DEVICE INTERRUPT	DINTR	Interrupt service request input from the peripheral device. An interrupt request is generated by the DMAC if this input is high and the device interrupt enable bit in the command register is also set.
40	$\overline{\text{INTERRUPT REQUEST}}$	$\overline{\text{INTR}}$	Active low interrupt service request output. This output goes low if: 1) Any one of the three interrupt conditions is active, and 2) The $\overline{\text{STOPR}}$ input is high, and 3) The corresponding interrupt enable bit for the interrupting condition is set.

NOTE: The following pins float when not active low and require an external pull-up resistor of 10 K Ω (or greater) to +5 VDC:

$\overline{\text{INTR}}$, $\overline{\text{REPLY}}$, $\overline{\text{RE}}$, $\overline{\text{WE}}$, $\overline{\text{MEMR}}$, $\overline{\text{MEMW}}$, $\overline{\text{MSYNC}}$

The following pins have internal 10 K Ω pull-up resistors to +5 VDC:

TBD, DRQ, DINTR

WIRE-ORABLE SIGNALS

The following output signals can be wired together with a single common pull-up resistor if multiple DMAC chips exist on the same board:

MSYNC, MEMR, MEMW, INTR

REGISTER SELECTION

A 4-bit address input (A0, A1, A2, A3) is used to select one of 8 internal DMAC registers or to generate a device chip select (DCS) output signal for selection of up to 8 peripheral device registers. The following table details the selection process.

INPUTS					OUTPUT	SELECTED REGISTER
<u>C\overline{S}</u>	A3	A2	A1	A0	<u>DCS</u>	
L	L	X	X	X	L	One of 8 peripheral device registers
L	H	L	L	L	H	DMAC control register (0)
L	H	L	L	H	H	DMAC status register (1)
L	H	L	H	L	H	DMAC TC low register (2)
L	H	L	H	H	H	DMAC TC high register (3)
L	H	H	L	L	H	DMAC MA low register (4)
L	H	H	L	H	H	DMAC MA high register (5)
L	H	H	H	L	H	DMAC MA ext. register (6)
L	H	H	H	H	H	DMAC ID code register (7)

NOTE: L = Low voltage level, H = High voltage level, X = don't care.

TRANSFER COUNT REGISTER (TCR)

A 16-bit counter register that holds the two's complement of the transfer count (words or bytes) for DMA transfer operations. The low order 8 bits are in TC low, and the high order 8 bits are in TC high. The count is incremented by one after every DMA transfer. When the count reaches zero, bit 3 of the Status Register is set to a one. If bit 3 in the Command Register is also a one then INTR will go low (providing STOPR is also high). TCR is set to a one on a MASTER RESET to allow a 64K transfer count during auto load.

MEMORY ADDRESS REGISTER (MAR)

An 18-bit counter register that occupies 3 DMA registers. Bits 0-7 are in MA low, bits 8-15 are in MA high, and bits 16-17 are in MA ext. The carry from bit 15 to 16 is enabled if and only if bit 6 of the Command Register is set to a one. If the BOW input pin is high then the MAR is incremented by one after every DMA transfer. If the BOW input pin is low then the MAR is incremented by two after every transfer and bit 0 is forced to a zero. This register is cleared to all zeros on a MASTER RESET.

During a DMA operation the DMA address is gated onto the DAL lines in two 9-bit bytes. The first byte out contains MAR 8-15 on DAL 0-7 and MAR 17 or AE8. The second byte out contains MAR 0-7 on DAL 0-7 and MAR 16 on AE8. The first byte is valid on the trailing edge of BUSR, and the second byte is valid on the trailing edge of LAL. Note that the address can easily be extended to 24 bits by decoding the address of the 2-bit extension register externally and gating the 6 unused bits into an external latch. This would give the system 16Mbytes of addressing with either 65K or 256K bytes of paging.

REGISTER DEFINITIONS

DMAC CONTROL REGISTER (CR)

DMAC CONTROL REGISTER (CH)															
7		6		5		4		3		2		1		0	
N/A		AECE		HBUS		IOM		TCIE		TOIE		DIE		RUN	
BIT		SYMBOL		FUNCTION											
0		RUN		Run/stop bit. A 1 places the DMAC in the run mode. A 0 terminates <u>DMAC</u> operation.											
1		DIE		Device interrupt enable. A 1 allows a high input on <u>DINTR</u> to set the <u>INTR</u> output low.											
2		TOIE		Time-out interrupt enable. A 1 allows the time-out one-shot to set the <u>INTR</u> output low. The time-out interrupt is set during a DMA transfer if <u>REPLY</u> does not go low within 5 usec of <u>MSYNC</u> going low.											
3		TCIE		Transfer count zero interrupt enable. A 1 allows a zero in the transfer count register to set the <u>INTR</u> output low.											
4		IOM		Input or output mode. A 1 sets <u>READ</u> mode (from the peripheral device to memory), and a 0 sets <u>WRITE</u> mode (from memory to the peripheral device). This bit also appears as an ungated output on the R/W pin.											
5		HBUS		Hold bus. A 1 informs the DMAC to hold onto the bus for the entire block instead of releasing the bus after each byte or word transfer.											

BIT	SYMBOL	FUNCTION
6	AECE	Address extension carry enable. A 1 allows a carry from DMA address bit 15 to propagate into bit 16.
7	N/A	Not used.

NOTE: Bits 1, 2, 3 set $\overline{\text{INTR}}$ low on an active condition if and only if the $\overline{\text{STOPR}}$ input is high.

DMAC STATUS REGISTER (SR)

7	6	5	4	3	2	1	0
BUSY	AECE	HBUS	IOM	TCZI	TOI	DINT	BOW
BIT	SYMBOL	FUNCTION					
0	BOW	Byte or word data channel. A read only bit that indicates the status of the BOW input pin. A 1 bit indicates byte mode, and the DMA memory address is incremented by one after each DMA transfer. A 0 bit indicates word mode, and the DMA memory address is incremented by two (bit 0 is forced to a 0) after every DMA transfer.					
1	DINT	If set a device interrupt has occurred. This is a read/write bit. Resetting this bit to a zero will reset $\overline{\text{INTR}}$.					
2	TOI	If set a time-out interrupt has occurred. This is a read/write bit. Resetting this bit to a zero will reset $\overline{\text{INTR}}$.					
3	TCZI	If set a transfer count equals zero interrupt has occurred. A read only bit. Sets EOB output when set.					
4	IOM	Input-output mode. This bit reflects the status of bit 4 in the Command Register. A read only bit.					
5	HBUS	Hold bus. This bit reflects the status of bit 5 in the Command Register. A read only bit.					
6	AECE	Address extension carry enable. This bit reflects the status of bit 6 in the Command Register. A read only bit.					
7	BUSY	Busy (data transfer not completed). A read only bit that reflects the status of bit 0 (RUN) in the Command Register.					

NOTE: Bits 1, 2, 3 are set if the corresponding condition occurs. The enable bits in the CR affect only the $\overline{\text{INTR}}$ output, and not the Status Register.

ID CODE REGISTER (IDR)

An 8-bit programmable interrupt ID code register that gives the system an efficient way to establish a jump or vector address during a DMAC interrupt. The register is cleared to all zeros during a MASTER RESET, and must be loaded by the program during system initialization. If $\overline{\text{INTR}}$ is low, and $\overline{\text{IACKI}}$ and $\overline{\text{RE}}$ go low then the contents of this register are gated onto DAL 0-7. $\overline{\text{IACKI}}$ and $\overline{\text{CS}}$ must not be allowed to be low at the same time.

MASTER RESET

All register bits are reset to a zero during a MASTER RESET except the following which are set to ones: TCR bit 0, CR4, CR5, CR6, SR4, SR5, and SR6. This sets up the DMAC for a 64K transfer from the peripheral device to memory starting at address 0. The hold bus mode is also enabled. Execution of an Auto Load will begin DMA transfers under the above conditions.

AUTO LOAD

If the AUTLD input is made active after a MASTER RESET then bits CR3, CR1, and CR0 are also set. This places the DMAC in run mode, and enables two of the interrupt conditions. The DMAC will initiate data transfers, and will continue until either the transfer count reaches zero or a device interrupt occurs. Either event will terminate transfers and generate an interrupt.

WRITE PROTECT FEATURE

During CPU controlled transfers to the DMAC, if the RUN bit is set then any attempt to write into any of the Memory Address or Transfer Count registers will result in a NOP. $\overline{\text{REPLY}}$ will be made low in any case.

CPU CONTROLLED DATA TRANSFERS

During a CPU controlled transfer the CPU must have control of the system bus. When a CPU cycle is

initiated the system decodes the address on the bus. If the DMAC or its associated peripheral device is selected then \overline{CS} to the DMAC is made low. The DMAC looks at the A3 input. If A3 is low the peripheral device is selected, and \overline{DCS} is made low. The DMAC will not respond to an active \overline{RE} or \overline{WE} if A3 is low, and the DAL bus will stay in a high impedance state. This allows the DMAC DAL bus and the device DAL bus to be tied together if the device DAL bus is also in a high impedance state when the device is not selected.

If A3 is high when \overline{CS} is low then the DMAC is selected and will respond to an active low \overline{RE} or \overline{WE} . A0-A2 selects the DMAC as described under the REGISTER SELECTION section. If \overline{RE} goes low the DMAC places the contents of the selected register on the DAL bus and activates \overline{REPLY} to inform the CPU that valid data is on the bus. If \overline{WE} goes low the DMAC gates the contents of the DAL bus into the selected register and activates \overline{REPLY} to inform the CPU that data has been accepted.

If the peripheral device has more than 8 registers, or the device has fewer than 8 registers and there are one or more auxiliary registers external to the device, then it may be easier for the user to separate DMAC and device chip selects. In this mode \overline{CS} to the DMAC is activated if and only if the DMAC is selected and A3 is tied to +5 VDC. The chip select to the device from a CPU controlled data transfer is ORed with \overline{DCS} out of the DMAC. In this mode \overline{DCS} will go low if and only if a DMA transfer is in effect and can be used by the controller as a "DMA ACTIVE" signal. Note that in any case actual data transfers to and from the CPU and the peripheral device are done by way of the device's DAL bus, not the DMAC's DAL bus.

DMAC CONTROLLED DATA TRANSFERS

When the DMAC is in RUN mode (CR0=1) it waits for a Data Request (DRQ) input from the peripheral device. When DRQ becomes active the DMAC requests the bus from the CPU by activating \overline{BUSR} . If \overline{STOPR} was active when DRQ went active then the DMAC would wait until \overline{STOPR} went high before activating \overline{BUSR} . When \overline{BACKI} goes low in response to an active \overline{BUSR} the request has been granted and the DMAC controls data transfers between the peripheral device and memory. The direction of the transfer is determined by the status of the $\overline{READ/WRITE}$ (R/W) output pin. Note that R/W is tied directly to CR4.

1.) DEVICE-TO-MEMORY DMA TRANSFERS (CR4=1)

Once the DMAC has been granted the bus the following occurs:

- A.) The DMAC places the high byte of the memory address on the DAL lines, activates \overline{DCS} , and then raises \overline{BUSR} . The trailing edge of \overline{BUSR} can be used to latch the address into an external buffer.
- B.) The DMAC places the low byte of the memory address on the DAL lines while activating \overline{LAL} , and then activates \overline{MSYNC} . The trailing edge of \overline{LAL} can be used to latch the address into an external buffer.
- C.) The DAL lines are placed into a high impedance state in anticipation of a data transfer across the bus.
- D.) The DMAC activates \overline{RE} and then activates \overline{MEMW} .
- E.) The DMAC waits for \overline{REPLY} to go low. When \overline{REPLY} is active the DMAC deactivates \overline{MEMW} and then deactivates \overline{RE} .
- F.) If the DMAC is *not* in hold bus mode (CR5=1) then the DMAC deactivates \overline{DCS} and gives up control of the bus. If the DMAC is in hold bus mode then \overline{DCS} remains low until after the completion of the final data transfer. Note that \overline{BUSR} still cycles for every transfer.
- G.) After the completion of every data transfer the memory address register is incremented by one in byte mode or two in word mode.
- H.) After the completion of every data transfer the transfer count is incremented by one. Transfers are considered to be completed when the transfer count equals zero.

2.) MEMORY-TO-DEVICE DMA TRANSFERS (CR4=0)

Once the DMAC has been granted the bus it goes through the same steps as in the DEVICE-TO-MEMORY mode with the exception of steps "D" and "E" which are as follows:

- D.) The DMAC activates \overline{MEMR} and then activates \overline{WE} .
- E.) The DMAC waits for \overline{REPLY} to go low. When \overline{REPLY} is active the DMAC deactivates \overline{WE} and then deactivates \overline{MEMR} .

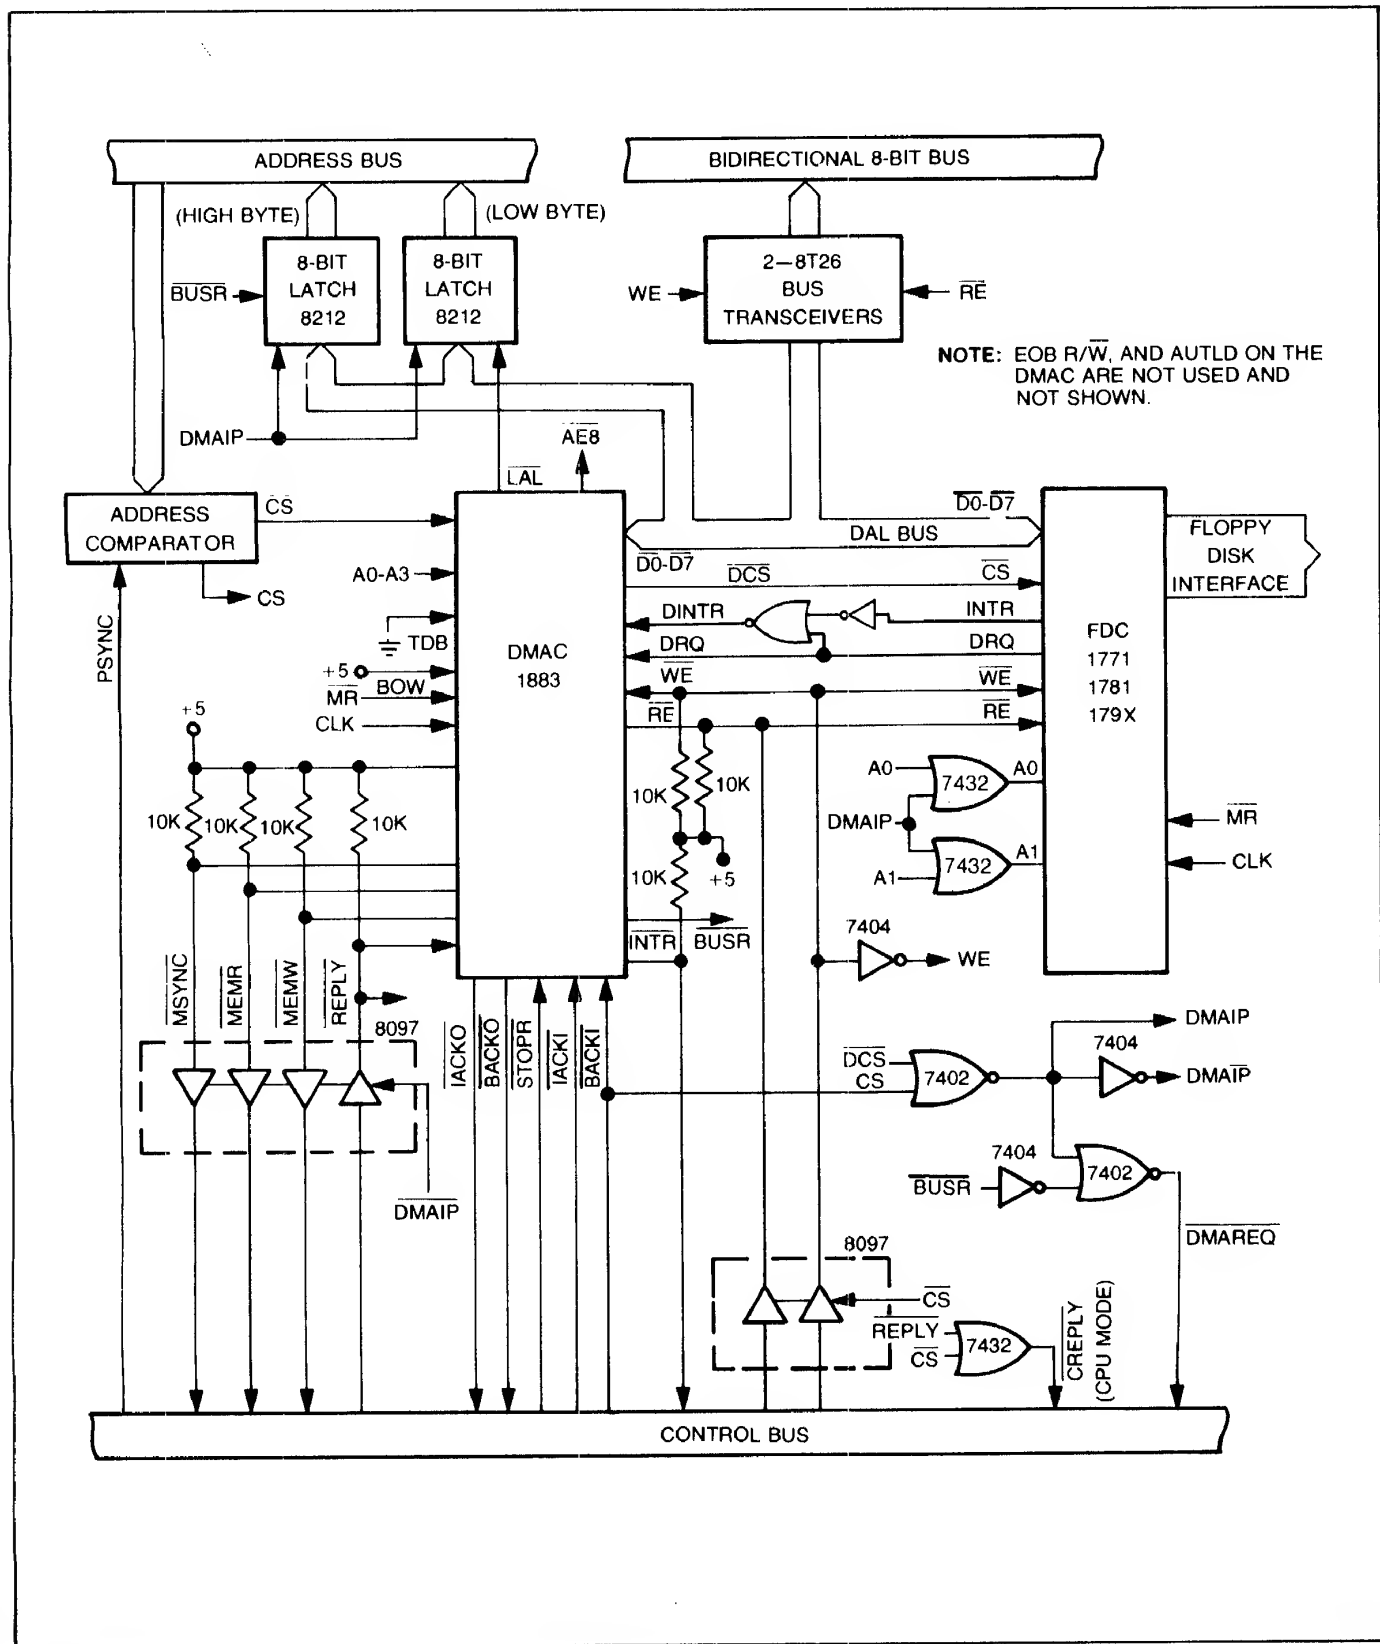

In either mode \overline{BACKI} will be gated out to \overline{BACKO} as soon as the DMAC deactivates \overline{DCS} . This allows other devices in the chain to gain access to the bus immediately.

INTERRUPTS

There are three individually enabled interrupt conditions. If any of the conditions occurs it will set its corresponding bit in the Status Register. If the

appropriate enable bit in the Command Register is set then $\overline{\text{INTR}}$ is also activated. Note that these are independent functions. When $\overline{\text{INTR}}$ is active then the

DMAC can be selected by an active $\overline{\text{IACKI}}$ instead of an active $\overline{\text{CS}}$. $\overline{\text{CS}}$ and $\overline{\text{IACKI}}$ must not both be active at the same time.

TYPICAL DMAC TO FDC APPLICATION

closest to the CPU on the daisy chain has highest priority for all request cycles.

NOTE: $\overline{\text{BACKI}}$ and $\overline{\text{STOPR}}$ can be dropped at the same time with no effect on the priority scheme, but the CPU may have to capture new requests until $\overline{\text{DCS}}$ goes high.

Rotating Priority

This is a daisy chain approach that prevents one device from getting most of the bus grants if multiple devices are active at the same time. In this mode any device requesting the bus causes the CPU to activate $\overline{\text{BACKI}}$. This signal is tied to the $\overline{\text{BACKI}}$ and $\overline{\text{STOPR}}$ inputs of the first DMAC. The $\overline{\text{BACKO}}$ output of the first DMAC goes to the $\overline{\text{BACKI}}$ and $\overline{\text{STOPR}}$ inputs of the second DMAC, and so on. The $\overline{\text{BACKO}}$ output of

the last DMAC in the chain goes back to the CPU to reset its $\overline{\text{BACKI}}$ output. In this mode the first device cannot request again until all other requesting devices in the chain have also been serviced.

In any case, if the CPU has to have the DMA request held active throughout the DMA cycle then the user will have to create this signal on the controller thusly: $\text{DMAREQ} = \text{BUSR} + (\text{DCS} \cdot \overline{\text{CS}})$. If the device and DMAC chip selects are generated on the controller separately then the $\overline{\text{CS}}$ can be eliminated from the equation. It is needed only to distinguish a CPU chip select from a DMA cycle chip select. Note that in either case the second term in the equation is equivalent to "DMA CYCLE IN PROGRESS" (DMAIP).

SPECIFICATIONS

Absolute Maximum Ratings

Ambient Temperature Under Bias... 0°C to $+70^{\circ}\text{C}$
Voltage on Any Pin with Respect
to Ground -0.5V to $+7\text{V}$
Power Dissipation 0.6 Watt

NOTE: Maximum ratings indicate limits beyond which permanent damage may occur. Continuous operation at these limits is not intended and should be limited to those conditions specified under dc electrical characteristics.

DC Electrical Characteristics

$T_A = 0^{\circ}\text{C}$ to $+70^{\circ}\text{C}$; $V_{CC} = 5.0\text{V} \pm 5\%$; $\text{GND} = 0\text{V}$

SYMBOL	PARAMETER	MIN.	TYP.	MAX.	UNIT	TEST CONDITIONS
V_{IL}	Input Low Voltage	-0.5		0.8	V	
V_{IH}	Input High Voltage	2.4		V_{CC}	V	
V_{OL}	Output Low Voltage			0.45	V	$I_{OL} = 1.6\text{ mA}$
V_{OH}	Output High Voltage	2.4			V	$I_{OH} = -100\text{ }\mu\text{A}$
I_{DL}	Data Bus Leakage			-50	μA	$V_{IN} = 0.45\text{V}$
				10	μA	$V_{IN} = V_{CC}$
I_{IL}	Input Leakage			10	μA	$V_{IN} = V_{CC}$
I_{CC}	Power Supply Current		45	90	mA	

NOTE: $V_{OL} \leq 0.4\text{V}$ when interfacing with low power Schottky parts ($I_{OL} < 1\text{ mA}$).

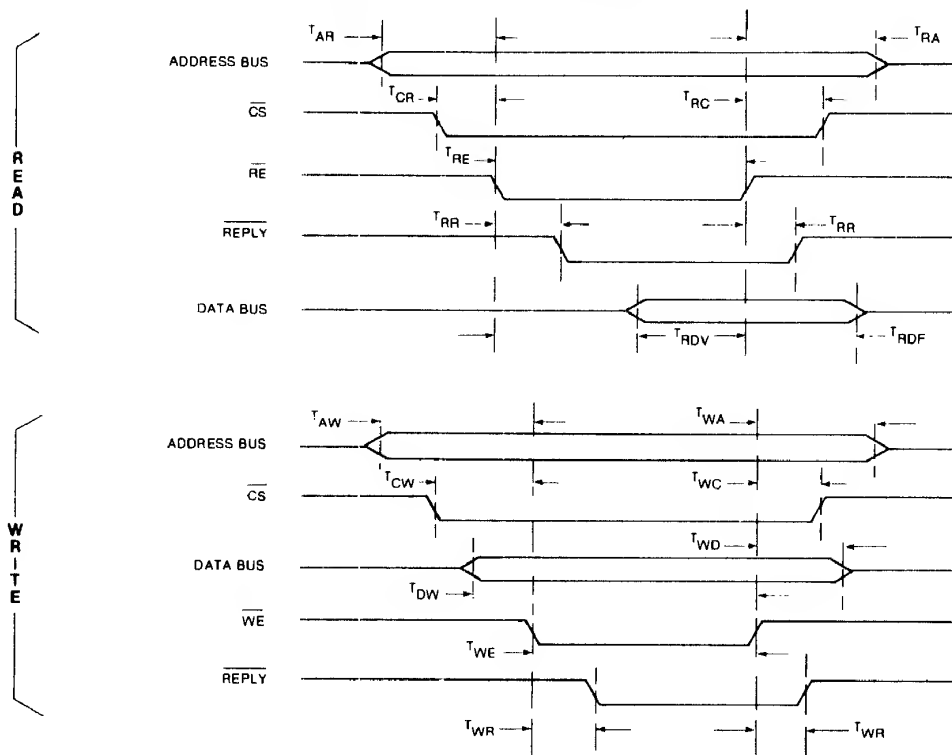

Capacitance

$T_A = 25^{\circ}\text{C}$; $V_{CC} = \text{GND} = 0\text{V}$

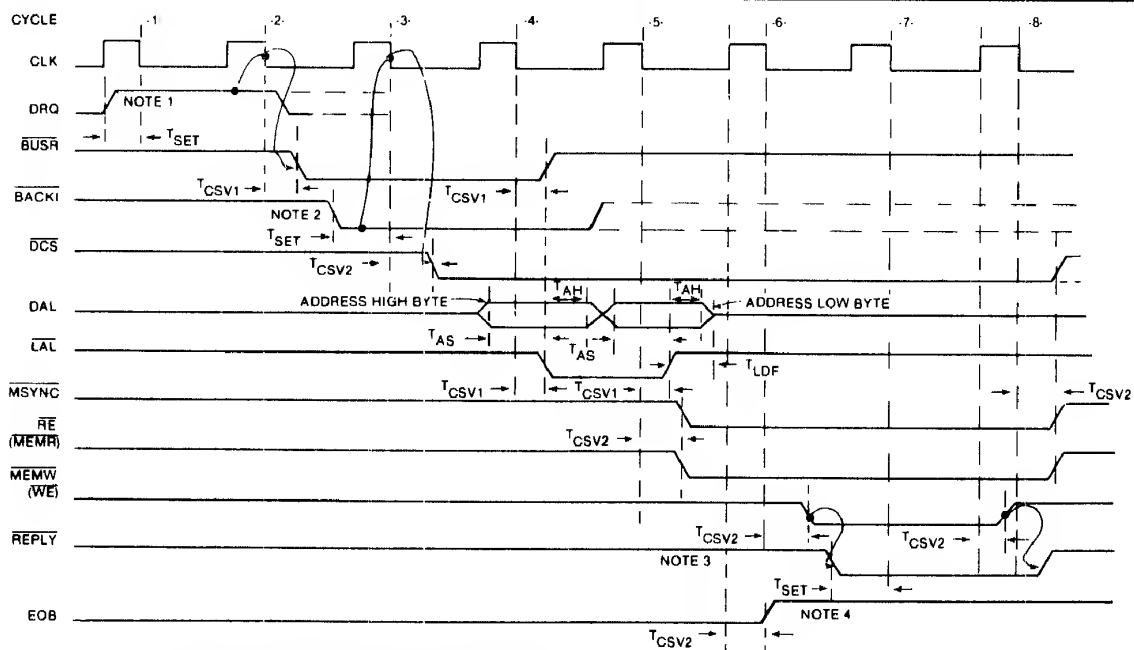

SYMBOL	PARAMETER	MIN.	TYP.	MAX.	UNIT	TEST CONDITIONS
C_{IN}	Input Capacitance			10	pF	$f_C = 1\text{ MHz}$
$C_{I/O}$	I/O Capacitance			20	pF	Unmeasured pins returned to GND.

System Clock (CLK) Characteristics

Maximum Frequency = 2.0 MHz
Minimum Pulse Width = 250 ns
Maximum Pulse Width = 50% of duty cycle

CPU CONTROLLED TRANSFER

- NOTES:**
1. BUSR \downarrow FOLLOWS SECOND CLK - AFTER DRZ \uparrow .
 2. a. CYCLE 2 IS SKIPPED FOR ALL SUBSEQUENT TRANSFERS WHEN IN THE HOLD MODE, I.E., DCS REMAINS LOW FOR ENTIRE BLOCK OF TRANSFERS.
b. FOLLOWING BUSR \downarrow WITH DCS HIGH (I.E., REQUESTING BUS CONTROL), THE DMA WILL ADD WAIT CYCLES BETWEEN CYCLES 2 AND 3 UNTIL BACK1 \downarrow IS RECEIVED.
 3. CYCLE 7 WILL BE REPEATED FOR EACH ADDITIONAL PERIOD THAT REPLY \downarrow IS DELAYED TO THE DMA. CYCLE 7 WILL BE SKIPPED (I.E., MEMW (WE) PULSE WIDTH = 1/2 CLK PERIOD) IF REPLY IS MADE LOW PRIOR TO CLK \downarrow OF CYCLE 6 (E.G., REPLY TIED TO GND DURING DMA TRANSFER).
 4. EOB IS ACTIVATED ONLY FOR THE TRANSFER WHERE TCR INCREMENTS FROM 11 ... 1 TO 00 ... 0 (I.E., END OF BLOCK).
 5. TO INSURE PROPER LOADING OF DAL BUS CONTENTS INTO THE CONTROLLER REGISTERS, THE WE PULSE WIDTH MUST BE GREATER THAN OR EQUAL TO ONE CLK PERIOD. THIS REQUIREMENT CAN ALSO BE SOLVED OFF CHIP BY TRIGGERING WE \uparrow (TRAILING EDGE) WITH CLK \downarrow .

DMA CONTROLLED TRANSFER TIMING

AC Electrical Characteristics

WD2143-03 Four Phase Clock Generator

WD2143-03

FEATURES

- IMPROVED VERSION OF WD2143-01
- TRUE AND INVERTED OUTPUTS
- SINGLE 5 VOLT SUPPLY
- TTL COMPATIBLE
- ON CHIP OSCILLATOR
- TTL CLOCK INPUT
- TTL CLOCK OUTPUTS
- PROGRAMMABLE PULSE WIDTHS
- PROGRAMMABLE PHASE WIDTHS
- NO EXTERNAL CAPACITOR

GENERAL DESCRIPTION

The WD2143-03 Four-Phase Clock Generator is a MOS/LSI device capable of generating four phase clocks. The output pulse widths are controlled by tying an external resistor to the proper control inputs. All pulse widths may be set to the same width by tying the ϕPW line through an external resistor. Each pulse width can also be individually programmed by tying a resistor through the appropriate $\phi 1PW$ — $\phi 4PW$ control inputs.

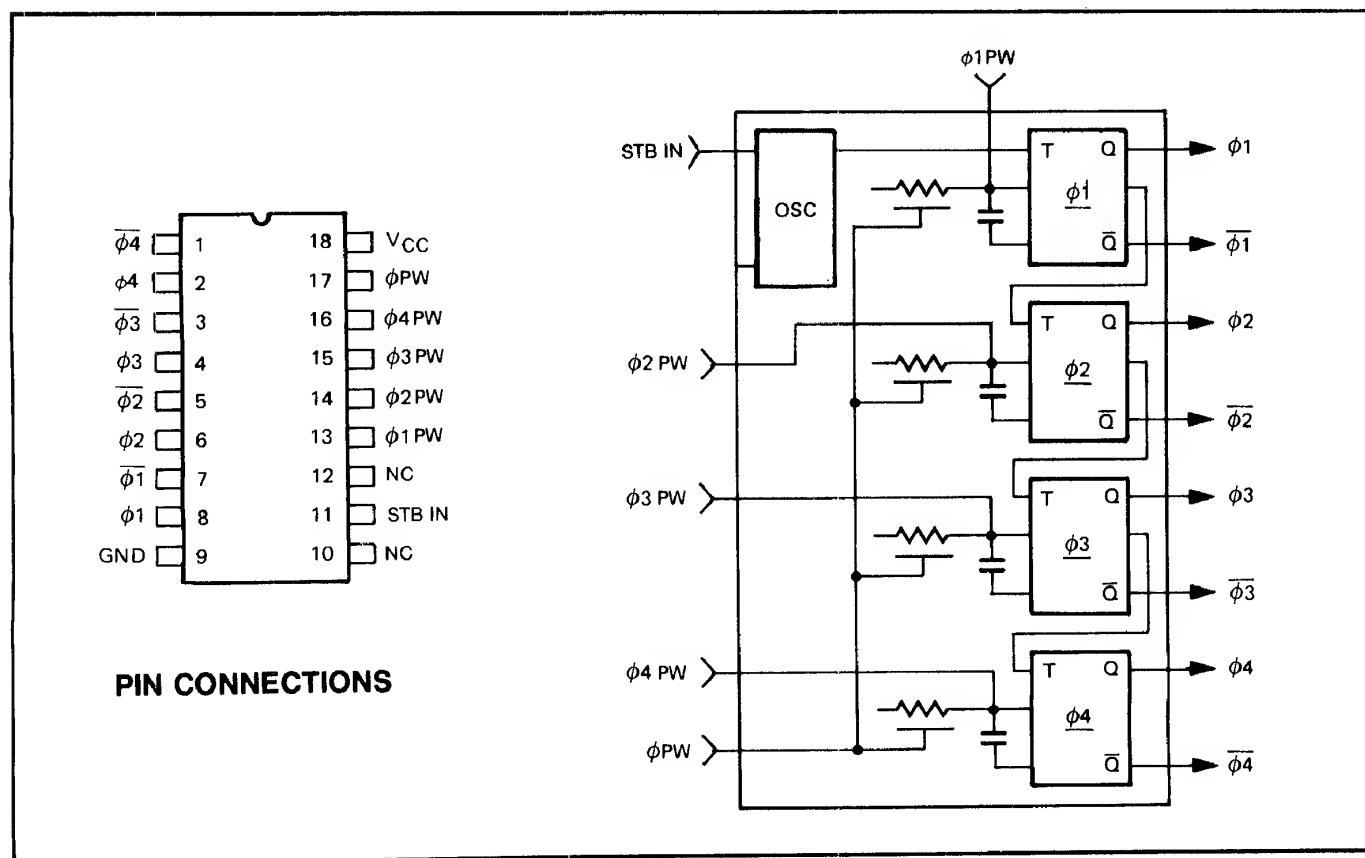

Figure 1 WD2143-03 PIN CONNECTIONS AND BLOCK DIAGRAM

DEVICE OPERATION

Each of the phase outputs can be controlled individually by tying an external resistor from $\phi 1PW$ — $\phi 4PW$ to a +5V supply. When it is desired to have $\phi 1$ through $\phi 4$ outputs the same width, the $\phi 1PW$ — $\phi 4PW$ inputs should be left open and an external resistor tied from the ϕPW (Pin 17) input to +12V.

STROBE IN (pin 11) is driven by a TTL square wave. Each of the four phase outputs provide both true and inverted signals, capable of driving 1 TTL load each.

PIN NUMBER	SYMBOL	DESCRIPTION
1, 3, 5, 7	$\overline{\phi 1} - \overline{\phi 4}$	Four phase clock outputs. These outputs are inverted (active low).
2, 4, 6, 8	$\phi 1 - \phi 4$	Four Phase clock outputs. These outputs are true (active high).
9	GND	Ground
10	NC	No connection
11	STB IN	Input signal to initiate four-phase clock outputs.
12	NC	No connection
13-16	$\phi 1PW - \phi 4PW$	External resistor inputs to control the individual pulse widths of each output. These pins can be left open if ϕPW is used.
17	ϕPW	External resistor input to control all phase outputs to the same pulse widths.
18	V_{CC}	+5V \pm 5% power supply input

SPECIFICATIONS

Absolute Maximum Ratings

Operating Temperature	0° to +70° C
Voltage on any pin with respect to Ground*	-0.5 to +7V
Power Dissipation	1 Watt
Storage Temperature	plastic -55° to +125° C ceramic -65° to +150° C

Note: Maximum ratings indicate limits beyond which permanent damage may occur. Continuous operation at these limits is not intended and should be limited to the DC electrical characteristics specified.

*Pin 17 = -0.5V to +12V. Increasing voltage on Pin 17 will decrease T_{pw} .

DC ELECTRICAL CHARACTERISTICS

$V_{CC} = 5V \pm 5\%$, $GND = 0V$, $T_A = 0^\circ$ to $70^\circ C$.

SYMBOL	PARAMETER	MIN.	MAX.	UNITS	CONDITIONS
V_{OL}	TTL low level output		0.4	V	$i_{OL} = 1.6 \text{ mA}$
V_{OH}	TTL high level output	2.0		V	$i_{OH} = -100 \mu A$
V_{IL}	STB in low voltage		0.8	V	
V_{IH}	STB in high voltage	2.4		V	
i_{CC}	Supply Current		80	mA	All outputs open

Table 2 DC ELECTRICAL CHARACTERISTICS

SWITCHING CHARACTERISTICS
 $V_{CC} = 5V \pm 5\%$, $GND = 0V$ $T_A = 0^\circ$ to $70^\circ C$

SYMBOL	PARAMETER	MIN.	MAX.	UNITS	CONDITIONS
t _{PD}	STB IN to $\emptyset 1$		140	ns	
t _{pw}	Pulse Width (any output)	100	300	ns	CL = 30pf
t _{PR}	Rise Time (any output)		30	ns	CL = 30pf
t _{PF}	Fall Time (any output)		25	ns	CL = 30pf
f _S	STROBE PULSE WIDTH		1.0	μs	combined t _{pw} = 400 ns
t _{DPW}	Pulse Width Differential		± 10	%	Referenced to $\emptyset 1$, 100-300 ns.

Table 3 SWITCHING CHARACTERISTICS

NOTE: T_{pw} measured at 50% V_{OH} Point; V_{OL} = 0.8V, V_{OH} = 2.0V.

WD9216-00/WD9216-01

Floppy Disk Data Separator — FDDS

PRELIMINARY

WD9216-00/WD9216-01

FEATURES

- PERFORMS COMPLETE DATA SEPARATION FUNCTION FOR FLOPPY DISK DRIVES
- SEPARATES FM OR MFM ENCODED DATA FROM ANY MAGNETIC MEDIA
- ELIMINATES SEVERAL SSI AND MSI DEVICES NORMALLY USED FOR DATA SEPARATION
- NO CRITICAL ADJUSTMENTS REQUIRED
- COMPATIBLE WITH WESTERN DIGITAL 179X, 176X AND OTHER FLOPPY DISK CONTROLLERS
- SMALL 8-PIN DUAL-IN-LINE PACKAGE
- + 5 VOLT ONLY POWER SUPPLY
- TTL COMPATIBLE INPUTS AND OUTPUTS

GENERAL DESCRIPTION

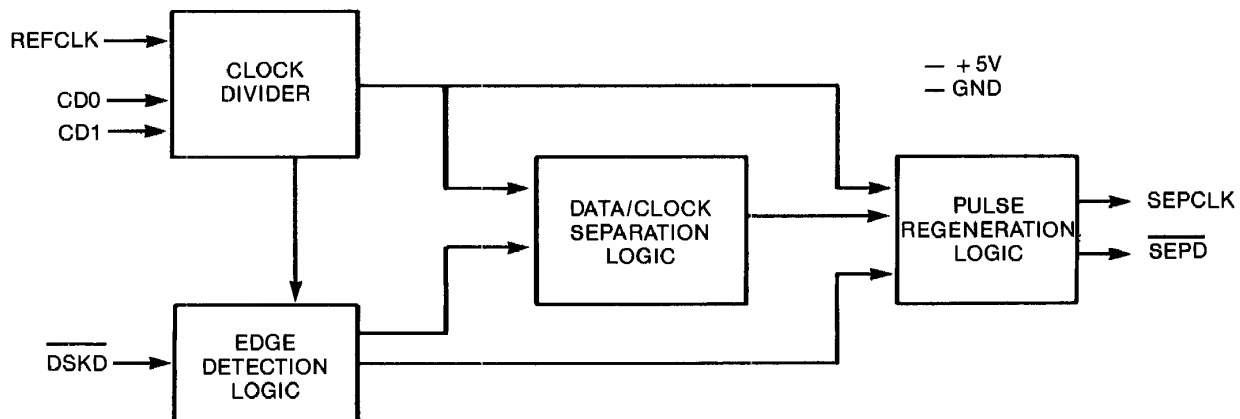

The Floppy Disk Data Separator provides a low cost solution to the problem of converting a single stream of pulses from a floppy disk drive into separate Clock and Data inputs for a Floppy Disk Controller.

The FDDS consists primarily of a clock divider, a long-term timing corrector, a short-term timing corrector, and reclocking circuitry. Supplied in an 8-pin Dual-In-Line package to save board real estate, the FDDS operates on + 5 volts only and is TTL compatible on all inputs and outputs.

The WD9216 is available in two versions; the WD9216-00, which is intended for 5¼" disks and the WD9216-01 for 5¼" and 8" disks.

ELECTRICAL CHARACTERISTICS**MAXIMUM RATINGS***

Operating Temperature Range..... 0°C to $+70^{\circ}\text{C}$
 Storage Temperature Range..... -55°C to 125°C
 Positive Voltage on any Pin,
 with respect to ground $+8.0\text{V}$
 Negative Voltage on any Pin,
 with respect to ground -0.3V

* Stresses above those listed may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or at any other condition above those indicated in the operational sections of this specification is not implied.

NOTE: When powering this device from laboratory or system power supplies, it is important that the Absolute Maximum Ratings not be exceeded or device failure can result. Some power supplies exhibit voltage spikes or "glitches" on their outputs when the AC power is switched on and off. In addition, voltage transients on the AC power line may appear on the DC output. If this possibility exists it is suggested that a clamp circuit be used.

OPERATING CHARACTERISTICS ($T_A = 0^{\circ}\text{C}$ to 70°C , $V_{CC} = +5\text{V} \pm 5\%$, unless otherwise noted)

DESCRIPTION OF PIN FUNCTIONS

PIN NUMBER	PIN NAME	SYMBOL	FUNCTION															
1	Disk Data	DSKD	Data input signal direct from disk drive. Contains combined clock and data waveform.															
2	Separated Clock	SEPCLK	Clock signal output from the FDDS derived from floppy disk drive serial bit stream.															
3	Reference Clock	REFCLK	Reference clock input.															
4	Ground	GND	Ground.															
5,6	Clock Divisor	CD0, CD1	CD0 and CD1 control the internal clock divider circuit. The internal clock is a submultiple of the REFCLK according to the following table: <table><tr><td>CD1</td><td>CD0</td><td>Divisor</td></tr><tr><td>0</td><td>0</td><td>1</td></tr><tr><td>0</td><td>1</td><td>2</td></tr><tr><td>1</td><td>0</td><td>4</td></tr><tr><td>1</td><td>1</td><td>8</td></tr></table>	CD1	CD0	Divisor	0	0	1	0	1	2	1	0	4	1	1	8
CD1	CD0	Divisor																
0	0	1																
0	1	2																
1	0	4																
1	1	8																
7	Separated Data	SEPD	SEPD is the data output of the FDDS															
8	Power Supply	VCC	+ 5 volt power supply															

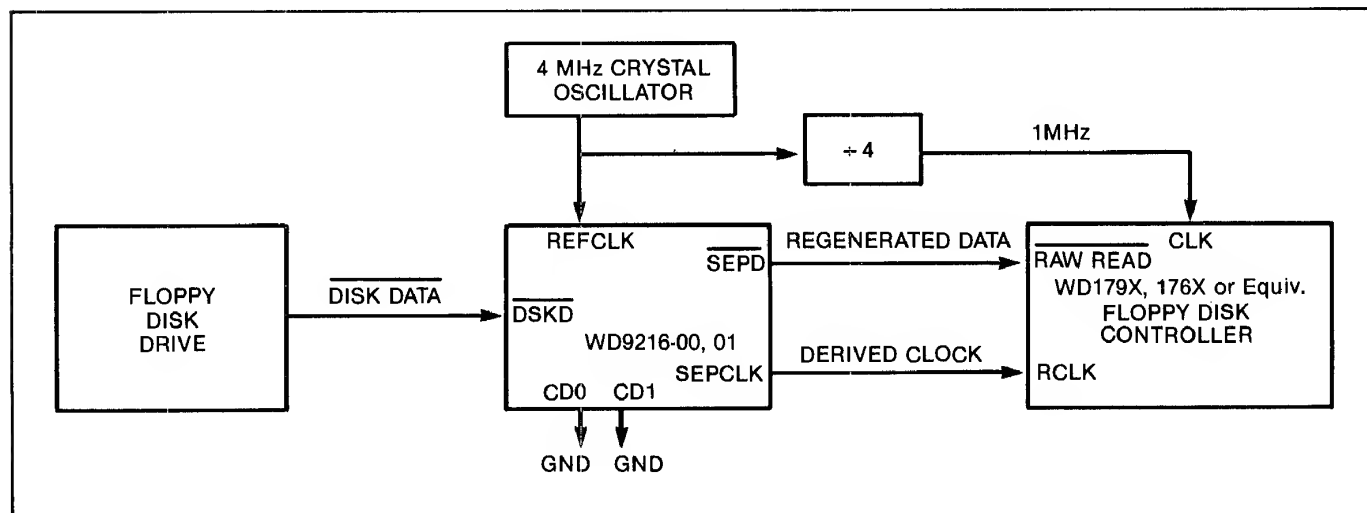

Figure 1.
TYPICAL SYSTEM CONFIGURATION
(5 1/4" Drive, Double Density)

OPERATION

A reference clock (REFCLK) of between 2 and 8 MHz is divided by the FDDS to provide an internal clock. The division ratio is selected by inputs CD0 and CD1. The reference clock and division ratio should be chosen per table 1.

The FDDS detects the leading edges of the disk data pulses and adjusts the phase of the internal clock to provide the SEPARATED CLOCK output.

Separate short and long term timing correctors assure accurate clock separation.

The internal clock frequency is nominally 16 times the SEPCLK frequency. Depending on the internal timing correction, the internal clock may be a minimum of 12 times to a maximum of 22 times the SEPCLK frequency.

The reference clock (REFCLK) is divided to provide the internal clock according to pins CD0 and CD1.

**TABLE 1:
CLOCK DIVIDER SELECTION TABLE**

DRIVE (8" or 5¼")	DENSITY (DD or SD)	REFCLK MHz	CD1	CD0	REMARKS
8	DD	8	0	0	} Select either one
8	SD	8	0	1	
8	SD	4	0	0	
5¼	DD	8	0	1	} Select either one
5¼	DD	4	0	0	
5¼	SD	8	1	0	} Select any one
5¼	SD	4	0	1	
5¼	SD	2	0	0
